Abstract

Many phenomena are described by bivariate signals or bidimensional vectors in applications ranging from radar to EEG, optics and oceanography. We show that an adequate quaternion Fourier transform permits to build relevant time-frequency representations of bivariate signals that naturally identify geometrical or polarization properties. First, a bivariate counterpart of the usual analytic signal of real signals is introduced, called the *quaternion embedding* of bivariate signals. Then two fundamental theorems ensure that a quaternion short term Fourier transform and a quaternion continuous wavelet transform are well defined and obey desirable properties such as conservation laws and reconstruction formulas. The resulting spectrograms and scalograms provide meaningful representations of both the time-frequency and geometrical/polarization content of the signal. Moreover the numerical implementation remains simply based on the use of FFT. A toolbox is available for reproducibility. Synthetic and real-world examples illustrate the relevance and efficiency of the proposed approach.

Keywords: Bivariate signal, Time-Frequency analysis, Quaternion Fourier Transform, Quaternion embedding, Polarization properties, Stokes parameters

1. Introduction

Bivariate signals are a special type of multivariate time series corresponding to vector motions on the 2D plane or equivalently in \mathbb{R}^2 . They are specific because their time samples encode the time evolution of vector valued quantities (motion or wavefield direction, velocity, etc). Non-stationary bivariate signals appear in many applications such as oceanography [1, 2], optics [3], radar [4], geophysics [5] or EEG analysis [6] to name but a few.

In most of these scientific fields, the physical phenomena (electromagnetic waves, currents, elastic waves, etc) are described by various types of quantities which depend on the frequency over different ranges of frequencies. As frequency components evolve with time, time-frequency representations are necessary to accurately describe the evolution of the recorded signal.

Over the last 20 years, several works have proposed to develop time-frequency representations of bivariate signals. Most authors have made use of *augmented* representations [7, 8], *i.e.* the real bivariate signal $[x(t), y(t)] \in \mathbb{R}^2$ or the complex version $[f(t), \bar{f}(t)] \in \mathbb{C}^2$ where $f(t) = x(t) + iy(t)$. The latter has been used to characterize second order statistics of complex valued processes [9] as well as higher order statistics [10, 11]. In both stationary and non-stationary cases, this approach leads to the extraction of kinematics and polarization properties of the signal [12, 8, 13, 14, 15]. In the deterministic setting, several bivariate

extensions of the Empirical Mode Decomposition (EMD) have been proposed [16, 17] to decompose bivariate signals into “simple” components¹. Bivariate instantaneous moments were introduced recently in [18] and further extended to the multivariate case in [19]. The bivariate instantaneous moment method permits to extract kinematic parameters from a bivariate signal. However, as noted by the authors in [18], this method is not applicable when the signal is multicomponent, *i.e.* consists of several monochromatic signals.

Existing methods all share the use of the standard complex Fourier transform (or complex-valued Cram r representation in the random case). In this article, we demonstrate that a different *deterministic* approach towards bivariate time-frequency analysis is possible thanks to an alternate definition of the Fourier transform borrowed from geometric algebra.

In the univariate case, *i.e.* when the signal is real-valued, it is well-known that its (complex) Fourier transform obeys Hermitian symmetry. This feature is fundamental for physical interpretation of the Fourier transform. In signal analysis it leads to the definition of the analytic signal [20, 21], which is the first building block towards more sophisticated time-frequency analysis tools. The analytic signal carries exactly the same information as the original real-valued signal, but with zeros in the negative frequency spectrum. Negative frequencies are redundant since they can be obtained by Hermitian symmetry from the positive frequencies spectrum. The analytic signal permits to define the *instantaneous amplitude* and the *instantaneous phase* of a real signal: it can be seen as the very first time-frequency analysis tool, at least for narrow-band signals.

In the bivariate case or when the signal is complex-valued, its (complex) Fourier transform lacks Hermitian symmetry. Both positive and negative frequencies have to be considered. This observation has motivated a type of analysis often called the *rotary spectrum*. In the simple case where the signal is stationary/periodic (depending from the setting, deterministic or random), the kinematic and polarization properties of the signal at frequency ω can be extracted from both spectrum values at ω and $-\omega$ [15, 8]. This approach involves a systematic parallel processing scheme of positive and negative frequencies. Physicists would prefer a tool that directly yields a representation of the bivariate signal content as a function of positive frequencies only. This is the desirable condition of a direct physical interpretation of the proposed representation, as in a spectrogram for instance.

In this work, we handle bivariate signals as complex-valued signals. We show that they can be efficiently processed using the Quaternion Fourier Transform (QFT), an alternate definition of the Fourier transform. As a first benefit, it restores a special kind of Hermitian symmetry in the quaternion spectral domain. The positive frequencies of the quaternion spectrum carry all the information about the bivariate signal. This permits the definition of the *quaternion embedding of a complex signal*, the bivariate counterpart of the analytic signal. This quaternion-valued signal is uniquely related to the original complex signal.

An interesting feature of quaternion-valued signals is that geometric information is easily accessible. Indeed, polar forms of quaternions permit the definition of *phases* to be interpreted geometrically. Much alike the phase and amplitude defined from an analytic signal, we will introduce the same type of parameters to describe complex-valued (*i.e.* bivariate) signals thanks to their *quaternion embedding*. It will appear that this description receives a direct geometrical interpretation. Even the usual Stokes’ parameters used by physicists to describe the polarization state of electromagnetic waves will arise as natural parameters.

Furthermore, the quaternion Fourier transform (QFT) permits to define time-frequency representations for multicomponent bivariate signals in a proper manner. We introduce the Quaternion Short-Term Fourier Transform (Q-STFT) and the Quaternion Continuous Wavelet Transform (Q-CWT) and provide new theorems demonstrating their ability to access geometric/polarization features of bivariate signals. The proposed approach leads to a consistent generalization of classical time-frequency representations to the case of bivariate signals. In practice, known concepts such as ridges extraction extend nicely to the bivariate case, revealing simultaneously time-frequency and polarization features of bivariate signals at a low computational cost since only FFT are needed still.

The paper is organized as follows. Section 2 first reviews usual quaternion calculus elements and introduces the Quaternion Fourier Transform (QFT) in a general setting. Then we consider the special case of bivariate signals and study this QFT. Section 3 introduces the quaternion embedding of a complex signal as

¹A component is here understood as a possibly time varying monochromatic signal.

	Symbol	Description
Operators	$\mathcal{F}\{f\}, \hat{f}$	Fourier transform of f
	$\mathcal{H}\{f\}$	Hilbert transform of f
	$f * g$	Convolution product between f and g (non commutative in general)
	Sf	Quaternion Short-Term Fourier transform of f
	Wf	Quaternion Continuous Wavelet Transform of f
Spaces	\mathbb{C}_μ	subfield $\mathbb{R} \oplus \mu\mathbb{R}$ isomorphic to \mathbb{C} , where μ is a pure unit quaternion.
	$L^p(\mathbb{R}, \mathbb{X})$	L^p -space of functions taking values in \mathbb{X}
	$H^2(\mathbb{R}, \mathbb{X})$	Hardy space of square integrable functions taking values in \mathbb{X}
	\mathcal{P}	Upper half-plane $\{(x, y) \in \mathbb{R}^2 y \geq 0\}$.

Table 1: List of symbols used throughout this work

well as a tailored polar form that recovers both the frequency content and polarization properties. Section 4 addresses some limitations of the quaternion embedding by introducing the Quaternion Short-Term Fourier Transform and the Quaternion Continuous Wavelet Transform. This section proves two fundamental theorems regarding time-frequency analysis of bivariate signals. Section 5 provides an asymptotic analysis and defines the ridges of the transforms presented in section 4. Section 6 illustrates the performances of these new tools on several examples of bivariate signals. A (non-exhaustive) summary of notations and symbols used throughout this paper is provided in Table 1. Appendices gather technical proofs.

2. The Quaternion Fourier Transform

2.1. Quaternion algebra

Quaternions were first described by Sir W.R. Hamilton in 1843 [22]. The set of quaternions \mathbb{H} is one of the four existing normed division algebras, together with real numbers \mathbb{R} , complex numbers \mathbb{C} and octonions \mathbb{O} (also known as Cayley numbers) [23]. Quaternions form a four dimensional noncommutative division ring over the real numbers. Any quaternion $q \in \mathbb{H}$ can be written in its Cartesian form as

$$q = a + b\mathbf{i} + c\mathbf{j} + d\mathbf{k}, \quad (1)$$

where $a, b, c, d \in \mathbb{R}$ and $\mathbf{i}, \mathbf{j}, \mathbf{k}$ are roots of -1 satisfying

$$\mathbf{i}^2 = \mathbf{j}^2 = \mathbf{k}^2 = \mathbf{i}\mathbf{j}\mathbf{k} = -1. \quad (2)$$

The canonical elements $\mathbf{i}, \mathbf{j}, \mathbf{k}$, together with the identity of \mathbb{H} form the quaternion canonical basis given by $\{1, \mathbf{i}, \mathbf{j}, \mathbf{k}\}$. Throughout this document, we will use the notation $\mathcal{S}(q) = a \in \mathbb{R}$ to define the *scalar part* of the quaternion q , and $\mathcal{V}(q) = q - \mathcal{S}(q) \in \text{span}\{\mathbf{i}, \mathbf{j}, \mathbf{k}\}$ to denote the *vector part* of q . As for complex numbers, we can define the real and imaginary parts of a quaternion q as

$$\Re(q) = a, \Im_{\mathbf{i}}(q) = b, \Im_{\mathbf{j}}(q) = c, \Im_{\mathbf{k}}(q) = d. \quad (3)$$

A quaternion is called *pure* if its real (or scalar) part is equal to zero, that is $a = 0$, *e.g.* $\mathbf{i}, \mathbf{j}, \mathbf{k}$ are pure quaternions. The quaternion conjugate of q is obtained by changing the sign of its vector part, leading to $\bar{q} = \mathcal{S}(q) - \mathcal{V}(q)$. The modulus of a quaternion $q \in \mathbb{H}$ is defined by

$$|q|^2 = q\bar{q} = \bar{q}q = a^2 + b^2 + c^2 + d^2. \quad (4)$$

When $|q| = 1$, q is called an *unit* quaternion. The set of unit quaternions is homeomorphic to $\mathcal{S}^3 = \{x \in \mathbb{R}^4 \mid \|x\| = 1\}$, the 3-dimensional unit sphere in \mathbb{R}^4 . The inverse of a non zero quaternion is defined by

$$q^{-1} = \frac{\bar{q}}{|q|^2}. \quad (5)$$

It is important to keep in mind that quaternion multiplication is noncommutative, that is in general for $p, q \in \mathbb{H}$, one has $pq \neq qp$.

Involutions with respect to $\mathbf{i}, \mathbf{j}, \mathbf{k}$ play an important role, and are defined as

$$\bar{q}^{\mathbf{i}} = -\mathbf{i}q\mathbf{i}, \bar{q}^{\mathbf{j}} = -\mathbf{j}q\mathbf{j}, \bar{q}^{\mathbf{k}} = -\mathbf{k}q\mathbf{k}. \quad (6)$$

The combination of conjugation and involution with respect to an arbitrary pure quaternion $\boldsymbol{\mu}$ is denoted by

$$q^{*\boldsymbol{\mu}} \triangleq \overline{(\bar{q})}^{\boldsymbol{\mu}} = \overline{(\bar{q}^{\boldsymbol{\mu}})}, \quad (7)$$

and for instance $(a + b\mathbf{i} + c\mathbf{j} + d\mathbf{k})^{*\mathbf{j}} = a + b\mathbf{i} - c\mathbf{j} + d\mathbf{k}$.

The Cartesian form (1) is not the only possible representation for a quaternion. Most of the content of this paper is indeed based on other useful representations, which better reflect the geometry of \mathbb{H} . First, we introduce the Cayley-Dickson form, which decomposes a quaternion q into a pair of 2D numbers isomorphic to a pair of complex numbers. The most general Cayley-Dickson form of a quaternion reads

$$q = q_1 + q_2\boldsymbol{\mu}_{\perp}, \quad q_1, q_2 \in \mathbb{C}_{\boldsymbol{\mu}}, \quad (8)$$

where $\mathbb{C}_{\boldsymbol{\mu}} \equiv \mathbb{R} \oplus \boldsymbol{\mu}\mathbb{R}$ is a complex subfield of \mathbb{H} isomorphic to \mathbb{C} . Here $\boldsymbol{\mu}$ and $\boldsymbol{\mu}_{\perp}$ are pure unit orthogonal quaternions: $\mathcal{S}(\boldsymbol{\mu}\boldsymbol{\mu}_{\perp}) = 0$. In particular, the decomposition given by the choice of $\boldsymbol{\mu} = \mathbf{i}$ and $\boldsymbol{\mu}_{\perp} = \mathbf{j}$ in (8) will be used extensively.

Just like the polar form of complex numbers, a quaternion Euler polar form can be defined². This form was first introduced by Bülow in [24]. Any quaternion q has a Euler decomposition which reads

$$q = |q| \exp(\mathbf{i}\theta) \exp(-\mathbf{k}\chi) \exp(\mathbf{j}\varphi), \quad (9)$$

where (θ, χ, φ) is called the *phase triplet* of q . The phase is (*almost uniquely*) defined within the interval

$$(\theta, \chi, \varphi) \in [-\pi/2, \pi/2] \times [-\pi/4, \pi/4] \times [-\pi, \pi[. \quad (10)$$

The term *almost* refers to the two singular cases for $\chi = \pm\pi/4$, where the phase of a quaternion is not well defined. This phenomenon is known as *gimbal lock*, since the three angles above are indeed the *xyz*-Euler angles corresponding to the rotation associated to the quaternion $q/|q|$ of unit norm³. Figure 1 presents the procedure to obtain the phase triplet (θ, χ, φ) . Table 2 summarizes important properties relevant to quaternion calculus.

2.2. Quaternion Fourier Transform

Most of the literature about *Quaternion Fourier transforms* concerns a particular type of Fourier transforms, namely for functions $f : \mathbb{R}^2 \rightarrow \mathbb{H}$. For a review on the subject, we refer the reader to [26] and references therein. This particular set of transforms is for instance of particular interest in color image processing [27]. It is worth noting that these transforms do not generally exhibit the same usual properties as the standard Fourier transform (*e.g.* convolution, inversion) [26]. This limits the use of such transforms in a broader setting.

In contrast, we review here the one-dimensional Quaternion Fourier transform, for functions $f : \mathbb{R} \rightarrow \mathbb{H}$. We show also some new results stressing how this transform extends the usual (complex) Fourier transform to quaternions, while maintaining reasonably good properties relevant to signal processing applications.

²The polar form presented here is rather different from what is often referred to as the polar form in the quaternion literature. It usually refers to the decomposition $q = |q| \exp(\boldsymbol{\mu}\theta)$, with $\boldsymbol{\mu}$ a pure unit quaternion and $\theta \in \mathbb{R}$.

³Recall that the unit sphere in \mathbb{R}^4 , \mathcal{S}^3 is indeed a two-fold covering of the rotation group $SO(3)$. That is every rotation matrix $\mathbf{R} \in SO(3)$ can be identified with two antipodal points on \mathcal{S}^3 , q and $-q$. Rotations can be described by three Euler angles [25], corresponding to three successive rotations around the canonical axes. The *xyz*-convention is used in this work.

Property	Description
$\mathcal{S}(q), \mathcal{V}(q)$	Scalar and Vector part of a quaternion q
\Re, \Im_i, \Im_j, \Im_k	Real and Imaginary parts operators
$ q ^2 = a^2 + b^2 + c^2 + d^2$	Squared modulus of q
$q^{-1} = \bar{q}/ q ^2$	Inverse ($q \neq 0$)
$\overline{pq} = \bar{q}\bar{p}$	Conjugate of a product
$\bar{q}^\mu = -\mu q \mu$	Involution by unit quaternion $\mu, \mu^2 = -1$
$q = q_1 + q_2 j$	Cayley-Dickson form of q
$e^{\mu\theta} = \cos \theta + \mu \sin \theta$	Exponential of a pure unit quaternion $\mu, \theta \in \mathbb{R}$
$q = q e^{i\theta}e^{-k\chi}e^{j\varphi}$	Euler polar form of q

Table 2: Basic guide to quaternion calculus. Here $q = a + bi + cj + dk$ is an arbitrary quaternion, μ is a pure unit quaternion $\mu^2 = -1$. The quantities θ, χ, φ are real-valued.

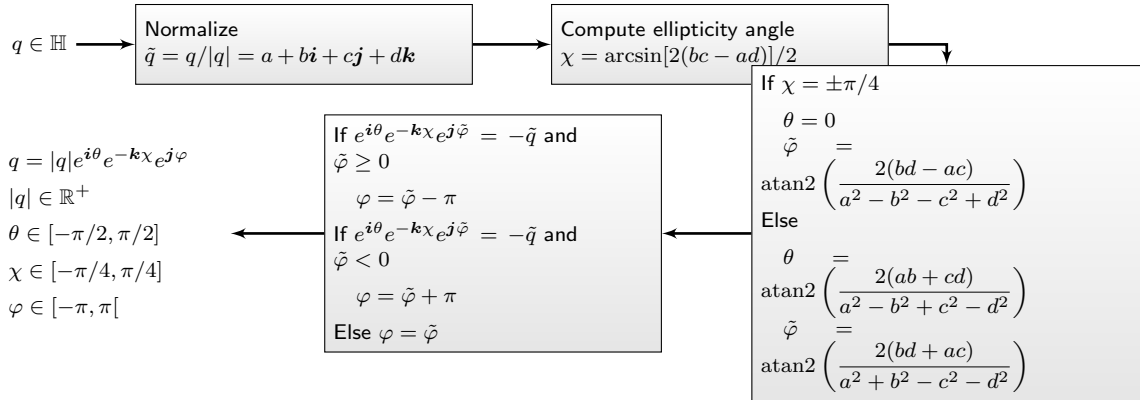

Figure 1: Computation of the Euler polar form parameters from a quaternion q . Adapted from [24].

We define the Quaternion Fourier Transform (QFT) of *axis* μ of a function $f : \mathbb{R} \rightarrow \mathbb{H}$ by

$$\mathcal{F}\{f\} = \int_{-\infty}^{+\infty} f(t) \exp(-\mu\omega t) dt \triangleq \hat{f}(\omega). \quad (11)$$

In comparison with the standard complex Fourier transform, there are several differences. The position of the exponential function is crucial due to the noncommutative product in \mathbb{H} , and in our work the exponential function will always be placed on the *right*. Moreover, the axis μ is a free parameter; it is only restricted to be a *pure unit quaternion*. Details on the choice of μ are given in section 2.4.

The existence and invertibility of the QFT have been studied by Jamison [28] in his PhD dissertation that dates back to 1970, for functions in $L^1(\mathbb{R}, \mathbb{H})$ and $L^2(\mathbb{R}, \mathbb{H})$. Although in his definition the exponential function is placed on the left, the proofs are straightforwardly adapted to our convention. We recall the fundamental results only, and refer to Jamison's manuscript for an extensive discussion.

As for the standard complex Fourier Transform, the existency and invertibility of the QFT are first proven for functions in $L^1(\mathbb{R}, \mathbb{H})$. The inverse QFT reads

$$f(t) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} \hat{f}(\omega) \exp(\mu\omega t) d\omega. \quad (12)$$

Using a density argument (see [29, Chapter 2] for instance) adapted to the present context, the extension of the QFT to functions in $L^2(\mathbb{R}, \mathbb{H})$ can be worked out, as well as its extension to generalized functions. The steps are identical to what is known in the complex case and will not be reproduced here.

One can show that $L^2(\mathbb{R}, \mathbb{H})$ is a (right) Hilbert space over \mathbb{H} [28, 30]. This will be of great interest, since from now on we will write inner products between functions $f, g \in L^2(\mathbb{R}, \mathbb{H})$

$$\langle f, g \rangle \triangleq \int_{-\infty}^{+\infty} f(t) \overline{g(t)} dt, \quad (13)$$

such that the induced norm reads

$$\|f\|^2 \triangleq \int_{-\infty}^{+\infty} |f(t)|^2 dt. \quad (14)$$

We now prove a fundamental theorem, which extends well-known results to the case of \mathbb{H} -valued functions.

Theorem 1 (Parseval and Plancherel formulas). *Let $f, g \in L^2(\mathbb{R}, \mathbb{H})$. Then the following holds*

$$(Parseval) \quad \begin{cases} \int_{-\infty}^{+\infty} f(t) \overline{g(t)} dt &= \frac{1}{2\pi} \int_{-\infty}^{+\infty} \hat{f}(\omega) \overline{\hat{g}(\omega)} d\omega \\ \int_{-\infty}^{+\infty} f(t) g(t)^{* \mu} dt &= \frac{1}{2\pi} \int_{-\infty}^{+\infty} \hat{f}(\omega) \hat{g}(\omega)^{* \mu} d\omega \end{cases}, \quad (15)$$

$$(Plancherel) \quad \begin{cases} \int_{-\infty}^{+\infty} |f(t)|^2 dt &= \frac{1}{2\pi} \int_{-\infty}^{+\infty} |\hat{f}(\omega)|^2 d\omega \\ \int_{-\infty}^{+\infty} f(t) f(t)^{* \mu} dt &= \frac{1}{2\pi} \int_{-\infty}^{+\infty} \hat{f}(\omega) \hat{f}(\omega)^{* \mu} d\omega \end{cases}. \quad (16)$$

Proof. See Appendix A.1. □

This theorem shows two things. It shows that the QFT is an isometry of $L^2(\mathbb{R}, \mathbb{H})$, an extension of a well-known result. It also shows that another quantity of geometrical nature is preserved by the QFT, the integral $\int_{-\infty}^{+\infty} f(t) f(t)^{* \mu} dt$. This is a new result which will permit powerful interpretations later on in the time-frequency analysis of bivariate signals.

2.3. General properties

We develop some properties related to the Quaternion Fourier Transform (QFT) of axis μ , for arbitrary functions in $L^2(\mathbb{R}, \mathbb{H})$. For brevity, most demonstrations are omitted, and we refer the reader to [27] for completeness.

Linearity. First, let us consider $f, g \in L^2(\mathbb{R}, \mathbb{H})$, and denote by \hat{f} and \hat{g} their Fourier transforms. It is straightforward to note that for all $\alpha, \beta \in \mathbb{H}$, the QFT of $\alpha f + \beta g$ is $\alpha \hat{f} + \beta \hat{g}$. Therefore the QFT is left-linear.

Scaling. Let $\alpha \in \mathbb{R}^*$. The QFT of the function $f(t/\alpha)$ is $|\alpha| \hat{f}(\alpha \omega)$, as can be checked by direct calculation.

Shifting. Let $\tau \in \mathbb{R}$, the QFT of $f(t - \tau)$ is $\hat{f}(\omega) e^{-\mu \omega \tau}$. Let $\omega_0 \in \mathbb{R}$, the QFT of $f(t) e^{\mu \omega_0 t}$ is $\hat{f}(\omega - \omega_0)$.

Derivatives. The QFT of the n -th derivative of f , $f^{(n)}$ is given by $\hat{f}(\omega)(\mu \omega)^n$. Note that multiplication by $(\mu \omega)^n$ is from the right, as the exponential kernel was placed on the right in the QFT definition (11).

Invariant subspace. An important feature of the QFT of axis μ defined in (11) is that the subspace $L^2(\mathbb{R}, \mathbb{C}_\mu) \subset L^2(\mathbb{R}, \mathbb{H})$ is an invariant subspace of the QFT of axis μ , that is $\mathcal{F}\{L^2(\mathbb{R}, \mathbb{C}_\mu)\} = L^2(\mathbb{R}, \mathbb{C}_\mu)$. This shows that the restriction of the QFT of axis μ to $L^2(\mathbb{R}, \mathbb{C}_\mu)$ defines a transform isomorphic to the well-known complex Fourier transform.

Convolution and product. Convolution is one of the cornerstone of signal processing. The following proposition gives the expression for the QFT transform of the convolution product under some conditions.

Proposition 1 (Convolution). *Let $f \in L^2(\mathbb{R}, \mathbb{H})$ and $g \in L^2(\mathbb{R}, \mathbb{C}_\mu)$ with respective QFT of axis μ denoted by \hat{f} and \hat{g} . Then the QFT of axis μ of the convolution product, $f * g$, is given by*

$$\mathcal{F}\{f * g\}(\omega) = \hat{f}(\omega) \hat{g}(\omega). \quad (17)$$

*Note that in this case the convolution product is not commutative, i.e. $f * g \neq g * f$, as f and g are now quaternion-valued functions.*

Proof. See Appendix A.2. □

Proposition 2 (Product). *Let $f \in L^2(\mathbb{R}, \mathbb{H})$ and $g \in L^2(\mathbb{R}, \mathbb{C}_\mu)$ with respective QFT of axis μ denoted by \hat{f} and \hat{g} . Then the QFT of axis μ of their product is given by*

$$\mathcal{F}\{fg\}(\omega) = \frac{1}{2\pi} (\hat{f} * \hat{g})(\omega). \quad (18)$$

Proof. Similar to the proof of the convolution property. □

Uncertainty principle. Of great importance is the uncertainty principle, also known as Gabor-Heisenberg uncertainty principle. First, considering a function $f \in L^2(\mathbb{R}, \mathbb{H})$ we define the temporal mean u like

$$u = \frac{1}{\|f\|^2} \int_{-\infty}^{+\infty} t |f(t)|^2 dt, \quad (19)$$

and the mean frequency ξ as

$$\xi = \frac{1}{2\pi \|f\|^2} \int_{-\infty}^{+\infty} \omega |\hat{f}(\omega)|^2 d\omega. \quad (20)$$

Spreads around these mean values are defined like

$$\sigma_t^2 = \frac{1}{\|f\|^2} \int_{-\infty}^{+\infty} (t - u)^2 |f(t)|^2 dt, \quad (21)$$

$$\sigma_\omega^2 = \frac{1}{2\pi \|f\|^2} \int_{-\infty}^{+\infty} (\omega - \xi)^2 |\hat{f}(\omega)|^2 d\omega. \quad (22)$$

Theorem 2 (Gabor-Heisenberg uncertainty principle). *Given a function $f \in L^2(\mathbb{R}, \mathbb{H})$ with QFT \hat{f} and time (resp. frequency) spread σ_t^2 (resp. σ_ω^2), then the following holds:*

$$\sigma_t^2 \sigma_\omega^2 \geq \frac{1}{4}. \quad (23)$$

Proof. See Appendix A.3. □

These fundamental properties show that the QFT has similar properties as the usual complex FT. The main difference lies in handling non-commutativity properly. In particular, this makes the QFT a well-behaved mathematical tool to process bivariate signals.

2.4. Bivariate signals and choice of the axis of the transform

It is well known that bivariate signals can be equivalently described as a pair of real signals or a single complex valued signal. For instance, given a bivariate signal $f(t)$,

$$f(t) = f_r(t) + \mathbf{i}f_i(t) \quad (24)$$

where $f_r(t)$ and $f_i(t)$ are real-valued is a valid decomposition for $f(t)$ in \mathbb{C}_i . Actually, any subfield \mathbb{C}_μ could have been used to decompose $f(t)$ as they are all isomorphic to the complex field. In the sequel, we will thus use the term bivariate, complex or \mathbb{C}_i -valued interchangeably depending on the context, and will assume that a bivariate signal f is of the form (24).

There are several possibilities for the choice of the axis μ of the QFT. If one chooses $\mu = \mathbf{i}$, then this is simply the classical complex Fourier transform. This shows that the QFT definition encompasses the standard complex case, but that it allows different choices as well. This point is interesting as it is well-known that the complex Fourier transform does not exhibit Hermitian symmetry when f is complex-valued. This prevents from defining standard time-frequency tools (*e.g.* the analytic signal) that rely on the Hermitian symmetry property of the transform.

It is interesting to wonder whether it is possible to obtain a transform that exhibits an “Hermitian-like” symmetry for a \mathbb{C}_i -valued signal. Proposition 3 below brings a positive answer. Writing down explicitly the QFT of axis μ for a signal as in (24), we have

$$\hat{f}(\omega) = \int f_r(t) \exp(-\mu\omega t) dt + \mathbf{i} \int f_i(t) \exp(-\mu\omega t) dt. \quad (25)$$

The key idea is now to treat *separately* the real and imaginary part of f in the QFT. That is, we would like to impose to the QFT to maintain the separation between real and imaginary parts of f in the frequency domain. This constraint is satisfied easily provided that μ is orthogonal to \mathbf{i} , that is $\mathcal{S}(\mathbf{i}\mu) = 0$. The simplest choice for μ is to take the second imaginary axis in \mathbb{H} , namely $\mu = \mathbf{j}$, and we will stick to this choice in the remaining of the paper. Therefore we choose to use the following QFT definition:

$$\hat{f}(\omega) = \int_{-\infty}^{+\infty} f(t) \exp(-\mathbf{j}\omega t) dt. \quad (26)$$

This QFT of a complex-valued signal exhibits a particular symmetry.

Proposition 3 (*i*-Hermitian symmetry). *Let $f : \mathbb{R} \rightarrow \mathbb{C}_i$, its QFT satisfies*

$$\hat{f}(-\omega) = -\mathbf{i}\hat{f}(\omega)\mathbf{i} = \overline{\hat{f}(\omega)}^{\mathbf{i}}. \quad (27)$$

Proof. We write $f(t) = f_r(t) + \mathbf{i}f_i(t)$, with $f_r(t)$ and $f_i(t)$ real-valued functions. Therefore, the QFT of axis \mathbf{j} of f gives

$$\hat{f}(\omega) = \hat{f}_r(\omega) + \mathbf{i}\hat{f}_i(\omega), \quad (28)$$

with \hat{f}_r, \hat{f}_i the QFTs of f_r, f_i respectively. Recall that f_r and f_i are real-valued functions so that $\hat{f}_r(\omega), \hat{f}_i(\omega)$ are \mathbb{C}_j -valued. Therefore, their QFT satisfy the usual Hermitian symmetry (as the QFT for real signals is isomorphic to the standard Fourier transform). As a result:

$$\hat{f}(-\omega) = \hat{f}_r(-\omega) + \mathbf{i}\hat{f}_i(-\omega) = \overline{\hat{f}_r(\omega)} + \overline{\mathbf{i}\hat{f}_i(\omega)} = -\mathbf{i}\hat{f}(\omega)\mathbf{i}. \quad (29)$$

The last equation is obtained recalling that if $z \in \mathbb{C}_j$, then $\mathbf{i}z = \bar{z}\mathbf{i}$. \square

This result is fundamental and will permit to construct the quaternion embedding of a complex signal in section 3. This result is, in regard of the Hermitian symmetry of the Fourier transform of real signals, the very first building block of nonstationary bivariate signal processing tools.

3. Quaternion embedding of complex-valued signals

For simple real-valued signals, it is natural to write $f(t) = a(t)\cos[\varphi(t)]$, where $a(t) \geq 0$ and $\varphi(t)$ are respectively identified as the *instantaneous amplitude* and *phase* [31, 32]. When the signal is richer, time-frequency analysis techniques aim to provide a set of pairs $[a_k(t), \varphi_k(t)]$ that faithfully describes the signal. Nevertheless, the decomposition $f(t) = a(t)\cos[\varphi(t)]$ is the simplest time-frequency model. It has many shortcomings, but understanding it is helpful in understanding how things work.

The analytic signal of f provides a well known way to associate to a simple real signal f an instantaneous amplitude $a(t)$ and phase $\varphi(t)$ [31]. It is obtained by suppressing negative frequencies from the spectrum [33, 34]. This operation is motivated by the Hermitian symmetry of the spectrum of real signals: the negative frequencies spectrum carries no additional information. This operation then permits to associate a unique *canonical* pair $[a(t), \varphi(t)]$ to the real signal f [33].

When the signal f takes complex values (*i.e.* is bivariate) the analytic signal approach is not directly applicable, since its spectrum no longer exhibits Hermitian symmetry. It was proposed in [18] to overcome this limitation by considering an analytic and anti-analytic signal, the latter being the analytic signal associated to the negative part of the spectrum. However, this approach has some inherent limitations due to the complex Fourier transform.

The usual complex Fourier transform brings some intrinsic ambiguity between *geometric content* and *frequency content*. For instance, a linear polarized signal f oscillating in the direction $\exp(\mathbf{i}\theta)$ at angular frequency ω can be written as

$$f(t) = \exp(\mathbf{i}\theta)\exp(\mathbf{i}\omega t) = \exp(\mathbf{i}\omega t + \mathbf{i}\theta). \quad (30)$$

One can read either f as a linearly polarized signal at pulsation ω in the direction $\exp(\mathbf{i}\theta)$, or as the analytic signal of $g(t) = \cos(\omega t + \theta)$. Therefore the geometric content (the direction of oscillation) is mixed with the frequency information.

The dimensionality of the complex field is actually responsible for not being able to separate directly the geometric from the frequency content. Using the QFT and the four dimensions of the quaternion algebra will permit to account for the geometric and frequency variables separately. Moreover, the \mathbf{i} -Hermitian symmetry (27) of the QFT of complex-valued signals will lead to the definition of a bivariate analogue of the analytic signal: the *quaternion embedding*.

We build upon the recent paper by one of the authors [35], in which the formal construction of the quaternion embedding signal was first presented, although named differently. The authors then used the recently introduced polar Cayley-Dickson form of a quaternion [36] to show that a complex signal is described by a canonical pair $[a(t), \varphi(t)]$, with $a(t)$ and $\varphi(t)$ taking complex values. While $a(t)$ is interpreted as the instantaneous complex amplitude, the instantaneous phase $\varphi(t)$ is restricted to be real, as the meaning of a complex instantaneous phase is not clearly interpretable. This restriction prevents from considering generic bivariate signals. In what follows we review the construction of the quaternion embedding signal, and present a novel approach that is generic and that circumvents previous issues of interpretability.

3.1. Definition

Definition 1 (Quaternion embedding of complex signals). Let $f : \mathbb{R} \rightarrow \mathbb{C}_i$. Its quaternion embedding f_+ is defined as

$$f_+(t) = f(t) + \mathcal{H}\{f\}(t)\mathbf{j}, \quad (31)$$

where $\mathcal{H}\{\cdot\}$ denotes the Hilbert transform

$$\mathcal{H}\{f\}(t) = \frac{1}{\pi} \text{p.v.} \int_{-\infty}^{+\infty} \frac{f(\tau)}{t - \tau} d\tau = \frac{1}{\pi} \text{p.v.} \int_{-\infty}^{+\infty} \frac{f_r(\tau)}{t - \tau} d\tau + \mathbf{i} \frac{1}{\pi} \text{p.v.} \int_{-\infty}^{+\infty} \frac{f_i(\tau)}{t - \tau} d\tau \quad (32)$$

where p.v. stands for Cauchy principal value.

By construction, f_+ is \mathbb{H} -valued. The original signal f is recovered in the $\{1, \mathbf{i}\}$ -components of f_+ , and the Hilbert transform of f is found in the $\{\mathbf{j}, \mathbf{k}\}$ part of f_+ . Let us compute the QFT of axis \mathbf{j} of the quaternion embedding f_+ :

$$\hat{f}_+(\omega) = \hat{f}(\omega) + \mathcal{F}\{\mathcal{H}\{f\}\}(\omega)\mathbf{j}, \quad (33)$$

which can be further decomposed since the quaternion Hilbert transform can be separated into two Hilbert transforms on the real and \mathbf{i} -imaginary parts of f respectively. As a consequence,

$$\mathcal{F}\{\mathcal{H}\{f_r\}\}(\omega) = -\text{sign}(\omega)\hat{f}_r(\omega)\mathbf{j}, \quad (34)$$

$$\mathcal{F}\{\mathcal{H}\{f_i\}\}(\omega) = -\text{sign}(\omega)\hat{f}_i(\omega)\mathbf{j}, \quad (35)$$

with \hat{f}_r, \hat{f}_i being \mathbb{C}_j -valued so that the QFT of the quaternion Hilbert transform of f reads

$$\mathcal{F}\{\mathcal{H}\{f\}\}(\omega) = -\text{sign}(\omega) \left(\hat{f}_r(\omega) + \mathbf{i}\hat{f}_i(\omega) \right) \mathbf{j} = -\text{sign}(\omega)\hat{f}(\omega)\mathbf{j}, \quad (36)$$

so that

$$\hat{f}_+(\omega) = (1 + \text{sign}(\omega))\hat{f}(\omega) = 2U(\omega)\hat{f}(\omega), \quad (37)$$

where $U(\omega)$ is the Heaviside unit step function. Equation (37) shows that: (i) the quaternion embedding of any complex-valued signal has a one-sided spectrum (ii) f and f_+ have the same frequency content in the positive frequencies region $\omega > 0$, up to a factor 2. These properties are direct continuations of those of the analytic signal of a real signal.

Let us define the real Hardy space $H^2(\mathbb{R}, \mathbb{H})$ such as

$$H^2(\mathbb{R}, \mathbb{H}) = \left\{ f \in L^2(\mathbb{R}, \mathbb{H}) \mid \hat{f}(\omega) = 0 \text{ for all } \omega < 0 \right\}. \quad (38)$$

By construction, the quaternion embedding f_+ of a complex signal $f \in L^2(\mathbb{R}, \mathbb{C}_i)$ belongs to $f_+ \in H^2(\mathbb{R}, \mathbb{H})$. More precisely, the quaternion embedding method establishes a one-to-one mapping between $L^2(\mathbb{R}, \mathbb{C}_i)$ and $H^2(\mathbb{R}, \mathbb{H})$, that is between a complex signal and its quaternion embedding.

3.2. Instantaneous amplitude, orientation, ellipticity and phase

To any real signal one can associate the canonical pair $[a(t), \varphi(t)]$ using the polar form of its analytic signal. We show here that one can associate a *canonical quadruplet* to any complex signal using its quaternion embedding, by means of an appropriate factorization.

The key idea is to decompose any quaternion embedding f_+ using the Euler polar form introduced in section 2.1:

$$f_+(t) = a(t) \exp[\mathbf{i}\theta(t)] \exp[-\mathbf{k}\chi(t)] \exp[\mathbf{j}\varphi(t)]. \quad (39)$$

This decomposition defines the *canonical quadruplet* $[a(t), \theta(t), \chi(t), \varphi(t)] \in \mathbb{R}^+ \times [-\pi/2, \pi/2] \times [-\pi/4, \pi/4] \times [-\pi, \pi]$ which fully describes the bivariate signal $f(t)$. By construction $f(t)$ is the projection of $f_+(t)$ onto \mathbb{C}_i so that

$$f(t) = a(t) \exp[\mathbf{i}\theta(t)] [\cos \varphi(t) \cos \chi(t) + \mathbf{i} \sin \varphi(t) \sin \chi(t)]. \quad (40)$$

Note the choice of the negative sign in (39), which leads to a positive second term in (40).

A clear physical interpretation of the canonical quadruplet $[a(t), \theta(t), \chi(t), \varphi(t)]$ is possible under some usual restrictions. We consider bivariate AM-FM signals, which can be seen as a thorough generalization of the AM-FM univariate signals. A (monocomponent) bivariate AM-FM signal is such that the variations of $\varphi(t)$ are much rapid than the rate of variation of the other components,

$$|\varphi'(t)| \gg |\chi'(t)|, |\theta'(t)|, |a'(t)/a(t)|. \quad (41)$$

The quantity $\varphi(t)$ is called the instantaneous phase of f . This choice is natural since $\varphi(t)$ appears in (9) along the same axis as the QFT, *i.e.* \mathbf{j} in our case. The instantaneous frequency of f is thus given by $\varphi'(t)$. The term $a(t)$ is referred to as the instantaneous amplitude. The two remaining terms are purely geometric, such that $\theta(t)$ represents the instantaneous orientation while $\chi(t)$ is to be interpreted as the instantaneous ellipticity.

Figure 2 depicts the ellipse traced out by the model (40) over time under condition (41). Over a short enough period of time, the quantities $a(t) = a$, $\theta(t) = \theta$ and $\chi(t) = \chi$ can thus be assumed as constants. The dot on the ellipse represents the value of the complex signal $f(t)$ at a fixed arbitrary time. The angle θ gives the orientation of the instantaneous ellipse. The amplitude a acts as a scale factor of this ellipse. The ellipticity angle χ controls the shape of the ellipse. If $\chi = 0$, the ellipse becomes a line segment, while if $\chi = \pm\pi/4$ one obtains a circle. The sign of $\chi(t)$ controls the direction of rotation in the ellipse. Finally, the angle $\varphi(t)$ gives the position of $f(t)$ on the ellipse. Section 3.4 explores further this model with some examples.

The ellipse parameters can evolve over time. The succession of instantaneous ellipses describe a three-dimensional tube (time being considered as an axis), and thus define the bivariate envelope of the signal.

Lilly and Olhede [18] have proposed a model similar to (40), called the Modulated Elliptical Signal (MES) model. It originates from oceanographic signal processing applications with a slightly different parametrization. The quaternion embedding method *a posteriori* justifies the relevance of this model.

3.3. Instantaneous Stokes parameters

There is a straightforward connection between the canonical quadruplet and the notion of polarization state in optics. The pair $[\theta(t), \chi(t)]$ represents exactly the spherical coordinates on the Poincaré sphere that describes the polarization state of the bivariate signal f . Since signals are here deterministic they are also said to be *fully polarized*.

In practice, one often characterizes the polarization state via the associated Stokes parameters [37, p. 31]. In optics, there are four Stokes parameters which read (in the case of fully polarized light)

$$S_0(t) = |a(t)|^2 \quad (42)$$

$$S_1(t) = |a(t)|^2 \cos 2\chi(t) \cos 2\theta(t), \quad (43)$$

$$S_2(t) = |a(t)|^2 \cos 2\chi(t) \sin 2\theta(t), \quad (44)$$

$$S_3(t) = |a(t)|^2 \sin 2\chi(t). \quad (45)$$

Here $S_0(t)$ is simply the instantaneous energy density of the signal. The three Stokes parameters S_1, S_2, S_3 decompose S_0 in terms of polarization content, as for all t , $S_0^2(t) = S_1^2(t) + S_2^2(t) + S_3^2(t)$. Note that the four Stokes parameters are energetic quantities.

In contrast with what is generally used in physics, the Stokes parameters defined here are time-dependent. In optics textbooks Stokes parameters are commonly defined as time-average values [37, Eq. (64), p. 554]: the time-averaging operator acts with respect to the oscillation of the electromagnetic field. Here, it corresponds to averaging only with respect to the instantaneous phase $\varphi(t)$. The so-defined *instantaneous Stokes* parameters thus describe evolving polarization properties.

The quaternion embedding f_+ leads naturally to the Stokes parameters of f . The first Stokes parameter is simply obtained by $|f_+(t)|^2 = S_0(t)$. Moreover basic quaternion arithmetic shows that

$$f_+(t)f_+(t)^{*j} = S_1(t) + \mathbf{i}S_2(t) - \mathbf{k}S_3(t), \quad (46)$$

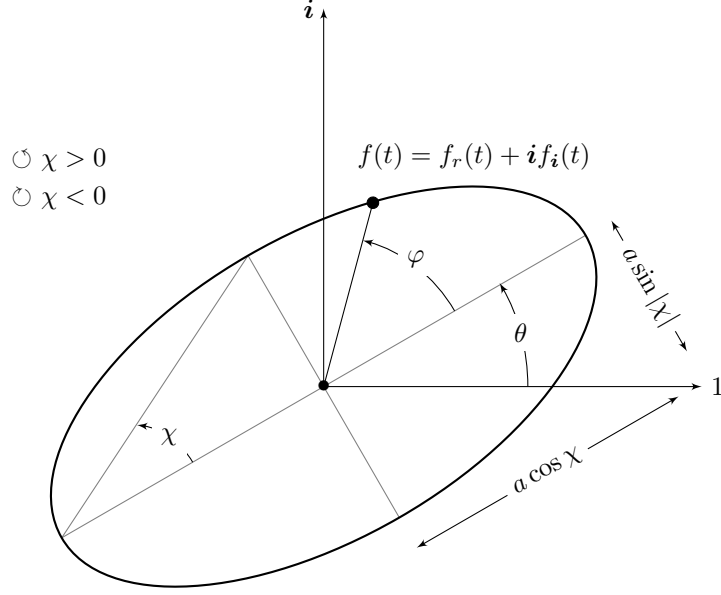

Figure 2: Representation of the signification of canonical quadruplet associated to a bivariate signal using its quaternion embedding.

so that the three remaining Stokes parameters are readily obtained from the quantity $f_+(t)f_+(t)^{*j}$. This allows to identify quantities of type $f_+(t)f_+(t)^{*j}$ as natural energetic measures of the polarization content of f , while $|f_+(t)|^2$ is simply an energy density. Note that the two quantities $|f(t)|^2$ and $f(t)f(t)^{*j}$ are also invariants of the QFT, as stated by the Parseval-Plancherel Theorem 1.

3.4. Examples

Equation (40) is the bivariate (polarized) counterpart of the well-known AM-FM model $a(t) \cos[\varphi(t)]$. Investigating which signals are generated by (40) is thus of great importance.

The simplest kind of bivariate signals obtained from (40) is the class of *monochromatic polarized signals*. In this case, the instantaneous phase is taken as $\varphi(t) = \omega_0 t$, $\omega_0 > 0$, while the other parameters are constant: $a(t) = a_0$, $\theta(t) = \theta_0 \in [-\pi/2, \pi/2]$ and $\chi(t) = \chi_0 \in [-\pi/4, \pi/4]$. Then

$$f(t) = a_0 \exp(i\theta_0) [\cos \chi_0 \cos(\omega_0 t) + i \sin \chi_0 \sin(\omega_0 t)]. \quad (47)$$

The angle θ_0 gives the orientation of the signal f . Now, browsing through possible values for χ_0 , we get

- $\chi_0 = 0$: linearly polarized signal, $f(t) = a_0 \exp(i\theta_0) \cos(\omega_0 t)$.
- $\chi_0 \in]-\pi/4, \pi/4[_{\setminus \{0\}}$: elliptical polarization, counterclockwise (CCW) if $\chi_0 > 0$, clockwise (CW) otherwise.
- $\chi_0 = \pm\pi/4$: circular polarization. It is the degenerate case of the Euler polar form. Then $\theta_0 = 0$, and the signal reads $f(t) = 2^{-1/2} a_0 \exp(\pm i\omega_0 t)$. Again, if $\chi_0 = \pi/4$ we have counterclockwise (CCW) polarization and clockwise (CW) if $\chi_0 = -\pi/4$.

Figure 3a shows an example of a polarized AM-FM signal specimen. Figure 3b show that this signal exhibits a linear chirp in frequency, along with both slowly varying instantaneous orientation and ellipticity. Namely, the instantaneous orientation is flipped slowly, while the instantaneous ellipticity evolves slowly from $\chi > 0$ to $\chi \simeq 0$.

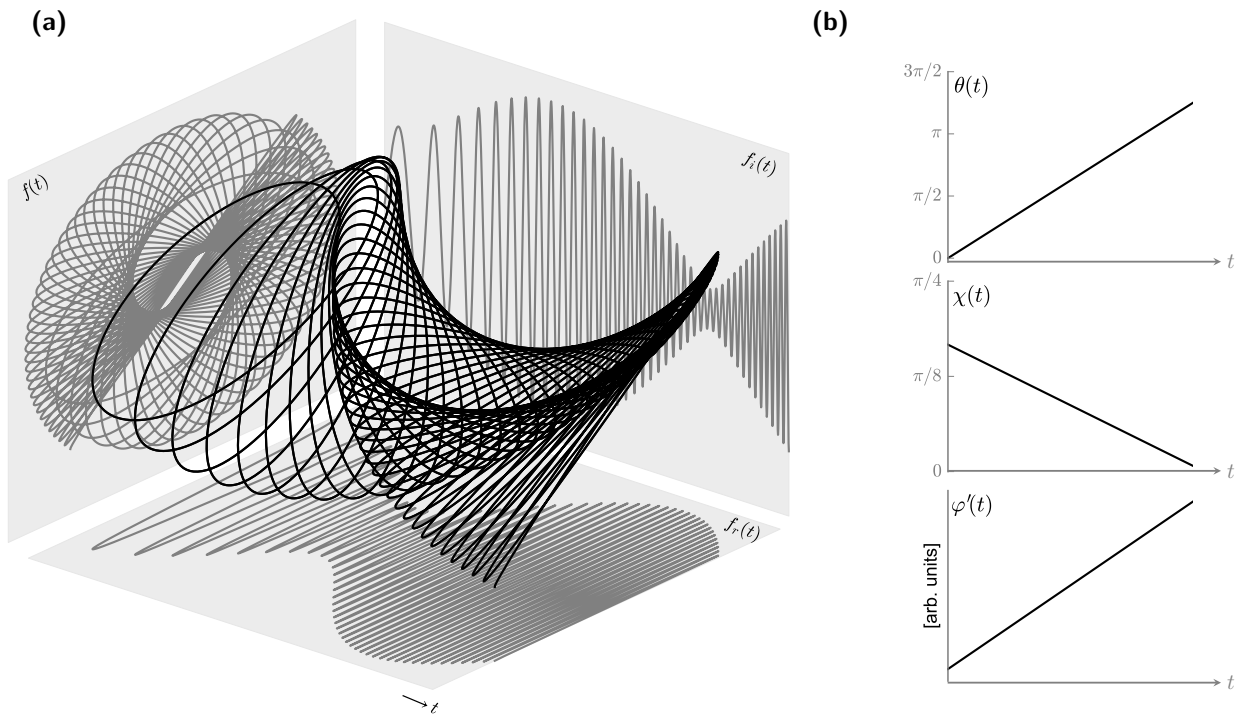

Figure 3: (a) Example of a signal generated via equation (40). For clarity, the bivariate signal has been developed in time along the third direction. Projection planes show respectively its complex plane trace, as well as real and imaginary components evolving with time. (b) Instantaneous orientation, ellipticity and phase associated with the bivariate signal. Here $|a(t)| = 1$.

3.5. Limitations

Exactly as in the univariate case, the quaternion embedding does not provide useful information when the signal is multicomponent. Consider the signal $f(t) = \alpha \cos \omega_0 t + \alpha \cos \omega_1 t$, with $\alpha \in \mathbb{R}^+$, which is a sum of two horizontally linearly polarized signals at angular frequencies ω_0 and ω_1 . Its quaternion embedding reads

$$f_+(t) = 2\alpha e^{j\omega_0 t} + 2\alpha e^{j\omega_1 t} = \alpha \cos\left(\frac{\omega_1 - \omega_0}{2}t\right) \exp\left(j\frac{\omega_0 + \omega_1}{2}t\right), \quad (48)$$

which gives us immediately the Euler polar form, with the canonical parameters given by $\chi(t) = \theta(t) = 0$, $a(t) = \alpha \cos\left(\frac{\omega_1 - \omega_0}{2}t\right)$ and $\varphi(t) = \frac{1}{2}(\omega_0 + \omega_1)t$. While $\chi(t) = 0$ and $\theta(t) = 0$ shows that the polarization is preserved by the sum, the values of $a(t)$ and $\varphi(t)$ poorly reflect the multicomponent nature of the signal f . When polarization states of each component differ, then a polarization mixing effect also appear in polar form of the quaternion embedding. This motivates the construction of dedicated time-frequency representations for bivariate signals.

4. Time-frequency representations of bivariate signals

We will focus here on two fundamental theorems, leaving the interpretation of such representations to Section 5. Examples illustrating the use of the newly introduced time-frequency representations will be given in Section 6.

Theorem 3 shows that the quaternion short-term Fourier transform defines a time-frequency representation for bivariate signals, allowing identification of time-frequency Stokes parameters. Theorem 4 shows similar results in the context of time-scale analysis of bivariate signals.

4.1. Quaternion Short-Term Fourier Transform

4.1.1. Definition and completeness

The quaternion embedding is unable to separate multiple components, so that we introduce the quaternion short-term Fourier transform (Q-STFT). In this section, we suppose that $f \in L^2(\mathbb{R}, \mathbb{H})$.

Let g be a real and symmetric normalized window, with $\|g\| = 1$. For $u, \xi \in \mathbb{R}$, its translated-modulated version is

$$g_{u,\xi}(t) = e^{j\xi t} g(t - u). \quad (49)$$

The exponential is on the left. This choice has no influence since g is real, but this is for convenience due to the permutation arising when taking the quaternion conjugate. The functions $g_{u,\xi}(t)$ define *time-frequency-polarization atoms*. The definition of $g_{u,\xi}$ is classical: the term *polarization* solely indicate that the atoms are \mathbb{C}_j -valued, rather than \mathbb{C}_i -valued.

The resulting Q-STFT of f is given by

$$Sf(u, \xi) = \langle f, g_{u,\xi} \rangle = \int_{-\infty}^{+\infty} f(t) g(t - u) e^{-j\xi t} dt. \quad (50)$$

This first fundamental theorem to build a time-frequency analysis of bivariate signals ensures energy conservation and reconstruction formula.

Theorem 3 (Inversion formula and energy conservation). *Let $f \in L^2(\mathbb{R}, \mathbb{H})$. Then the inversion formula reads*

$$f(t) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} Sf(u, \xi) g_{u,\xi}(t) d\xi du, \quad (51)$$

and the energy of f is conserved,

$$\int_{-\infty}^{+\infty} |f(t)|^2 dt = \frac{1}{2\pi} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} |Sf(u, \xi)|^2 du d\xi, \quad (52)$$

as well as the polarization properties of f :

$$\int_{-\infty}^{+\infty} f(t)f(t)^{*j}dt = \frac{1}{2\pi} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} Sf(u,\xi)Sf(u,\xi)^{*j}dud\xi. \quad (53)$$

Proof. See Appendix B.1. \square

This fundamental result extends classical results [29] to the bivariate setting. Equation (52) shows that $|Sf(u,\xi)|^2$ defines an energy density in the time-frequency plane. Equation (53) shows that the instantaneous state of polarization given by the Stokes parameters is conserved by the representation. Thus we can call the quantity $Sf(u,\xi)Sf(u,\xi)^{*j}$ the *polarization spectrogram* of f .

4.1.2. Redundancy: the RKHS structure

The Q-STFT does not span the whole functional space $L^2(\mathbb{R}^2, \mathbb{H})$, where \mathbb{R}^2 stands here for the time-frequency plane. It has a reproducing kernel Hilbert space (RKHS) structure. Writing the Q-STFT of some function $f \in L^2(\mathbb{R}, \mathbb{H})$, we have

$$Sf(u_0, \xi_0) = \int_{-\infty}^{+\infty} f(t)g(t - u_0)e^{-j\xi_0 t}dt \quad (54)$$

for some $(u_0, \xi_0) \in \mathbb{R}^2$. The inversion formula (51) yields

$$Sf(u_0, \xi_0) = \iint_{\mathbb{R}^2} Sf(u, \xi)K(u, \xi, u_0, \xi_0)dud\xi, \quad (55)$$

where we have introduced the kernel K

$$K(u, \xi, u_0, \xi_0) = \langle g_{u,\xi}, g_{u_0,\xi_0} \rangle. \quad (56)$$

Equation (55) shows that the image of $L^2(\mathbb{R}, \mathbb{H})$ by the Q-STFT is a RKHS with kernel K . Note that this result is a bivariate extension of a property of the usual STFT [29].

4.1.3. Examples

To understand the behavior of the Q-STFT, we look at two very simple signals. Section 5 will carry a more systematic interpretation of these results.

Monochromatic polarized signal. Let $f(t)$ such that its quaternion embedding reads $f_+(t) = a_0 \exp(i\theta_0) \exp(-\mathbf{k}\chi_0) \exp(j\omega_0 t)$, with $a_0 \in \mathbb{R}^+$, $\theta_0 \in [-\pi/2, \pi/2]$, $\chi_0 \in [-\pi/4, \pi/4]$ and $\omega_0 \in \mathbb{R}$. Its Q-STFT reads

$$Sf_+(u, \xi) = a_0 e^{i\theta_0} e^{-\mathbf{k}\chi_0} \hat{g}(\xi - \omega_0) e^{-j(\xi - \omega_0)u} \quad (57)$$

which is localized around the frequency $\xi = \omega_0$ in the time-frequency plane, as expected. The polarization spectrogram of f_+ is

$$Sf_+(u, \xi)Sf_+(u, \xi)^{*j} = |\hat{g}(\xi - \omega_0)|^2 \left[\underbrace{|a_0|^2 \cos 2\theta_0 \cos 2\chi_0}_{S_1} + \underbrace{i|a_0|^2 \sin 2\theta_0 \sin 2\chi_0}_{S_2} - \underbrace{\mathbf{k}|a_0|^2 \sin 2\chi_0}_{S_3} \right], \quad (58)$$

so that the polarization spectrogram of f_+ gives immediatly the three time-frequency Stokes parameters that fully characterize f_+ .

Polarized linear chirp. Consider a polarized linear chirp f , such that its quaternion embedding reads $f_+(t) = a_0 \exp(i\theta_0) \exp(-\mathbf{k}\chi_0) \exp(j\alpha t^2)$, with $a_0 \in \mathbb{R}^+$, $\theta_0 \in [-\pi/2, \pi/2]$, $\chi_0 \in [-\pi/4, \pi/4]$ and $\alpha \in \mathbb{R}$. When the window is gaussian, that is $g(t) = (\pi\sigma^2)^{-1/4} \exp[-t^2/(2\sigma^2)]$, it is possible to give a closed-form expression for $Sf_+(u, \xi)$ (see e.g. [29, p. 41]):

$$Sf_+(u, \xi) = a_0 e^{i\theta_0} e^{-\mathbf{k}\chi_0} \left(\frac{2\pi\sigma^2}{1 - j2\sigma^2\alpha} \right)^{1/2} \times \exp \left[-\frac{(\sigma^2/2)(\xi - 2\alpha u)^2}{1 + 4\sigma^4\alpha^2} \right] \exp \left[j \frac{-(\xi u - \alpha u^2) - \alpha\sigma^4\xi^2}{1 + 4\sigma^4\alpha^2} \right]. \quad (59)$$

It shows that $Sf_+(u, \xi)$ is localized in the time-frequency plane around the instantaneous frequency line of f , $\xi(u) = 2\alpha u$. The polarization spectrogram of f_+ is

$$Sf_+(u, \xi) Sf_+(u, \xi)^{*j} = C(\xi - 2\alpha u) \left[\underbrace{|a_0|^2 \cos 2\theta_0 \cos 2\chi_0}_{S_1} + \underbrace{i|a_0|^2 \sin 2\theta_0 \sin 2\chi_0}_{S_2} - \underbrace{\mathbf{k}|a_0|^2 \sin 2\chi_0}_{S_3} \right], \quad (60)$$

where C is a real function depending on the window. One obtains the time-frequency Stokes parameters of the signal.

4.2. Quaternion continuous wavelet transform

The fixed size in the time-frequency plane of Q-STFT atoms prevents from analysing a large range of frequencies over short time scales. Following classical theory, we will now introduce the quaternion continuous wavelet transform (Q-CWT). The wavelet atoms will be \mathbb{C}_j -valued, to *mimick* the Q-STFT atoms. The resulting quaternion continuous wavelet transform decouples geometric and frequency content.

4.2.1. Definition and completeness

Throughout this section, we restrict our analysis to the real Hardy space $H^2(\mathbb{R}, \mathbb{H})$ introduced in Section 3. Recall that one can associate to any $f \in L^2(\mathbb{R}, \mathbb{C}_i)$ a unique element $f_+ \in H^2(\mathbb{R}, \mathbb{H})$ called the quaternion embedding of f .

Definition 2 (Polarization wavelets). *A polarization wavelet is a \mathbb{C}_j -valued function $\psi \in H^2(\mathbb{R}, \mathbb{C}_j)$, normalized with $\|\psi\| = 1$ and centered at $t = 0$. Time-scale-polarization atoms are defined as translated-dilated versions of the wavelet ψ :*

$$\psi_{u,s}(t) = \frac{1}{\sqrt{s}} \psi \left(\frac{t-u}{s} \right). \quad (61)$$

The translation and dilation parameters run over the upper half-plane i.e. $(u, s) \in \mathcal{P}$ (see Table 1). These atoms are normalized, so that $\|\psi_{u,s}\| = 1$.

This definition is again classical. The term *polarization* indicates that the atoms are \mathbb{C}_j -valued, rather than \mathbb{C}_i -valued.

The quaternion continuous wavelet transform of a bivariate signal f at time u and scale s is:

$$Wf(u, s) = \langle f, \psi_{u,s} \rangle = \int_{-\infty}^{+\infty} f(t) \frac{1}{\sqrt{s}} \overline{\psi \left(\frac{t-u}{s} \right)} dt \quad (62)$$

The second fundamental theorem of this paper ensures energy conservation and the existency of an inversion formula for the quaternion continuous wavelet transform.

Theorem 4 (Inversion formula and energy conservation). *Let $f \in H^2(\mathbb{R}, \mathbb{H})$, and a polarization wavelet $\psi \in H^2(\mathbb{R}, \mathbb{C}_j)$. Suppose that the admissibility condition is satisfied, that is*

$$C_\psi = \int_0^{+\infty} \frac{|\hat{\psi}(\omega)|^2}{\omega} d\omega < \infty. \quad (63)$$

The inverse reconstruction formula reads

$$f(t) = C_\psi^{-1} \int_0^{+\infty} \int_{-\infty}^{+\infty} Wf(u, s) \frac{1}{\sqrt{s}} \psi\left(\frac{t-u}{s}\right) du \frac{ds}{s^2}, \quad (64)$$

and the energy is conserved,

$$\frac{1}{C_\psi} \int_0^{+\infty} \int_{-\infty}^{+\infty} |Wf(u, s)|^2 du \frac{ds}{s^2} = \|f\|^2, \quad (65)$$

as well as the polarization properties

$$\int_{-\infty}^{+\infty} f(t) f(t)^{*j} dt = \frac{1}{C_\psi} \int_0^{+\infty} \int_{-\infty}^{+\infty} Wf(u, s) Wf(u, s)^{*j} du \frac{ds}{s^2} \quad (66)$$

Proof. See Appendix B.2. \square

Equation (65) indicates that the quantity $|Wf(u, s)|^2$ can be interpreted as an energy density in the time-scale plane. Equation (66) means that the polarization properties of f are conserved by the representation. This leads to the definition of the *polarization scalogram*, which is the image of the coefficients $Wf(u, s) Wf(u, s)^{*j}$ in the time-scale plane.

While taking the wavelet $\psi \in H^2(\mathbb{R}, \mathbb{C}_j)$ is necessary to extract time-frequency (or time-scale) tones, the condition that $f \in H^2(\mathbb{R}, \mathbb{H})$ is not restrictive. Indeed, since there is a one-to-one correspondence between a bivariate signal $f \in L^2(\mathbb{R}, \mathbb{C}_i)$ and its quaternion embedding $f_+ \in H^2(\mathbb{R}, \mathbb{H})$, the results presented here are also valid for signals $f \in L^2(\mathbb{R}, \mathbb{C}_i)$. One then has

$$Wf(u, s) = \frac{1}{2} Wf_+(u, s). \quad (67)$$

Polarization wavelet design. Definition 2 is classical, and polarization wavelets are constructed similarly to classical analytic wavelets [29]. Namely, they can be built as the frequency modulation of a real, symmetric window g , which yields

$$\psi(t) = g(t) \exp(j\eta t) \quad (68)$$

which admits the QFT $\hat{\psi}(\omega) = \hat{g}(\omega - \eta)$. If $\hat{g}(\omega) = 0$ for $|\omega| > \eta$, then the wavelet belongs to $H^2(\mathbb{R}, \mathbb{C}_j)$.

4.2.2. RKHS structure

As with the Q-STFT, the image of $L^2(\mathbb{R}, \mathbb{H})$ by the Q-CWT does not span the whole $L^2(\mathcal{P}, \mathbb{H})$ space, where \mathcal{P} denotes the time-scale upper half-plane. Rather, it spans only a subspace of it, where the redundancy of the representation is encoded within a RKHS structure. Starting from the definition of the Q-CWT and plugging the inversion formula (64), one gets

$$Wf(u_0, s_0) = C_\psi^{-1} \int_0^{+\infty} \int_{-\infty}^{+\infty} Wf(u, s) K(u, s, u_0, s_0) du \frac{ds}{s^2}, \quad (69)$$

where we have introduced the kernel K which reads

$$K(u, s, u_0, s_0) = \langle \psi_{u,s}, \psi_{u_0,s_0} \rangle. \quad (70)$$

4.2.3. Example

Let $f(t)$ be such that its quaternion embedding reads $f_+(t) = a_0 \exp(i\theta_0) \exp(-\mathbf{k}\chi_0) \exp(j\omega_0 t)$, with $a_0 \in \mathbb{R}^+$, $\theta_0 \in [-\pi/2, \pi/2]$, $\chi_0 \in [-\pi/4, \pi/4]$ and $\omega_0 \in \mathbb{R}$. Its Q-CWT reads

$$Wf_+(u, s) = a_0 e^{i\theta_0} e^{-\mathbf{k}\chi_0} s^{1/2} \overline{\hat{\psi}(s\omega_0)} e^{j\omega_0 u} = a_0 e^{i\theta_0} e^{-\mathbf{k}\chi_0} s^{1/2} \overline{\hat{g}(s\omega_0 - \eta)} e^{j\omega_0 u} \quad (71)$$

which is localized around scale $s = \eta/\omega_0$ in the time-scale plane. On the line $s = \eta/\omega_0$, one has $Wf_+(u, \eta/\omega_0) = a_0 e^{i\theta_0} e^{-\mathbf{k}\chi_0} \eta^{1/2} \omega_0^{-1/2} \overline{\hat{g}(0)} e^{j\omega_0 u}$, so that the polarization information about f can be extracted directly from the Q-CWT coefficients. The polarization scalogram of f_+ is

$$Wf_+(u, s)Wf_+(u, s)^{*j} = s|\hat{\psi}(s\omega_0)|^2 \left[\underbrace{|a_0|^2 \cos 2\theta_0 \cos 2\chi_0}_{S_1} + \underbrace{i|a_0|^2 \sin 2\theta_0 \sin 2\chi_0}_{S_2} - \underbrace{\mathbf{k}|a_0|^2 \sin 2\chi_0}_{S_3} \right], \quad (72)$$

leading directly to time-frequency Stokes parameters.

5. Asymptotic analysis and ridges

The goal of this section is the so-called *ridge analysis*, that is to provide results about the energy localisation in the time-frequency plane (resp. time-scale plane) of bivariate signals. Ridge analysis has attracted much interest since the 90's. Early work from [38] provided an asymptotic approach. Subsequent theoretical results were developed in a more general setting in [29] and in the context of the analytic wavelet transform by [39].

The discussion here follows closely the approach presented in [38] for univariate signals. It relies upon an *asymptotic hypothesis* on the signal, which essentially means that condition (41) is satisfied: the phase is varying much faster than the geometric components. Finally, we will discuss how well known algorithms in ridge analysis can be applied to the bivariate setting.

5.1. Ridges of the quaternion short-term Fourier transform

The time-frequency-polarization atoms $g_{u,\xi}$ are of the form $g_{u,\xi}(t) = g(t - u) \exp(j\xi t)$, where g is a real, symmetric and normalized window. Under some conditions detailed in Appendix C.2, the *ridge* of the transform is given by the set of points $(u, \xi) \in \Omega$ such that

$$\xi = \xi_{\mathcal{R}}(u) = \varphi'(u). \quad (73)$$

It gives the instantaneous frequency of the signal. On the ridge, the Q-STFT becomes

$$Sf(u, \xi_{\mathcal{R}}(u)) \simeq \sqrt{\frac{\pi}{2}} f_+(u) \frac{g(0)}{\sqrt{|\varphi''(u)|}} e^{\text{sign}(\varphi''(u))j\frac{\pi}{4}} e^{-j\xi u}. \quad (74)$$

This shows that the Q-STFT is on the ridge simply the quaternion embedding of f up to some corrective factor with values in \mathbb{C}_j . As a consequence, assuming that the ridge has been extracted from the Q-STFT coefficients, the polarization properties of f are readily obtained from the polar Euler decomposition of $Sf(u, \xi_{\mathcal{R}}(u))$.

The polarization spectrogram on the ridge is

$$Sf(u, \xi_{\mathcal{R}}(u))Sf(u, \xi_{\mathcal{R}}(u))^{*j} \simeq \frac{\pi}{2} \frac{g(0)^2}{|\varphi''(u)|} f_+(u)f_+(u)^{*j}. \quad (75)$$

On the ridge, one has directly access to the instantaneous Stokes parameters of f_+ .

5.2. Ridges of the quaternion continuous wavelet transform

Recall that we consider wavelets $\psi(t) = g(t) \exp(j\eta t)$, where g is a real, symmetric window and $\eta > 0$ is the central frequency such that ψ belongs to $H^2(\mathbb{R}, \mathbb{C}_j)$. Under some conditions detailed in Appendix C.2, the *ridge* of the transform is given by the set of points $(u, \xi) \in \mathcal{P}$ such that

$$s = s_{\mathcal{R}}(u) = \frac{\eta}{\varphi'(u)}, \quad (76)$$

which again yields the instantaneous frequency of the signal. The restriction of the Q-CWT to the ridge is:

$$Wf(u, s_{\mathcal{R}}(u)) \simeq \sqrt{\frac{\pi}{2s_{\mathcal{R}}(u)}} f_+(u) \frac{g(0)}{\sqrt{|\varphi''(u)|}} e^{\text{sign}(\varphi''(u))j \frac{\pi}{4}}. \quad (77)$$

The Q-CWT on the ridge is simply the quaternion embedding of f up to some corrective factor with values in \mathbb{C}_j . Computing the Euler polar decomposition of $Wf(u, s_{\mathcal{R}}(u))$ immediatly gives the instantaneous polarization properties.

The polarization scalogram on the ridge is

$$Wf(u, s_{\mathcal{R}}(u))Wf(u, s_{\mathcal{R}}(u))^*j \simeq \frac{\pi}{2s_{\mathcal{R}}(u)} \frac{g(0)^2}{|\varphi''(u)|} f_+(u)f_+(u)^*j, \quad (78)$$

which again shows that the instantaneous Stokes parameters are available on the ridge of the polarization scalogram.

5.3. Ridge extraction and discussion

It is possible to show that the ridge can be extracted from the j -phase of the Q-STFT and Q-CWT coefficients, as originally suggested in the univariate case by [38] (not discussed here). This approach is known to have shortcomings when the signal-to-noise ratio is low, and other approaches have to be used instead [40, 41]. Existing ridge extraction algorithms can be thoroughly adapted to the bivariate setting.

A detailed discussion on ridge extraction methods is out the scope of the present paper. In our simulations we have used a heuristic method which identifies at each instant u the local maxima of the energy density in the time-frequency (resp. time-scale) plane. This method, although not optimal, provides reasonably good results for our purpose.

6. Time-frequency representations of bivariate signals: illustration

We finally illustrate the time-frequency representations presented in section 4 and the subsequent results in section 5. Two synthetic examples are presented, which are *polarized* counterparts of classical examples (see *e.g.* [29]). A real-world example is also provided.

Two equivalent time-frequency representations of bivariate signals can be proposed. The first one is directly related to classical frequency analysis. One can extract ridges from a time-frequency energy density. Instantaneous polarization properties are thus unveiled using the Euler polar form on these ridges. Another approach is to compute the polarization spectrogram (resp. polarization scalogram) of the signal. This gives the three time-frequency Stokes parameters of the signal.

We explore the benefits of the two methods. As they are equivalent representations, we will use the term *polarization spectrogram* (resp. *scalogram*) to denote one or the other.

6.1. Sum of linear polarized chirps

Consider a superposition of two linear chirps, each having its own polarization properties (79) and (80). The signal is defined on the time interval $[0, 1]$ by $N = 1024$ equispaced samples. It can be written as a the superposition $f(t) = f_1(t) + f_2(t)$, where their respective polar Euler decomposition reads

$$\theta_1(t) = \frac{\pi}{4}, \chi_1(t) = \frac{\pi}{6} - t, \varphi_1(t) = 50\pi t + 250\pi t^2 \quad (79)$$

$$\theta_2(t) = \frac{\pi}{4}10t, \chi_2(t) = 0, \varphi_2(t) = 150\pi t + 250\pi t^2 \quad (80)$$

This signal can be seen as a polarized version of the classical parallel linear chirps signal [29]. The Q-STFT was computed with a Hanning window of size 101 samples, providing good time-frequency clarity.

Figure 4 shows the two equivalent polarization spectrograms of f . Figure 4a, b and c depicts the three time-frequency Stokes parameters. Figure 4d, e and f show respectively the time-frequency energy density, instantaneous orientation and ellipticity.

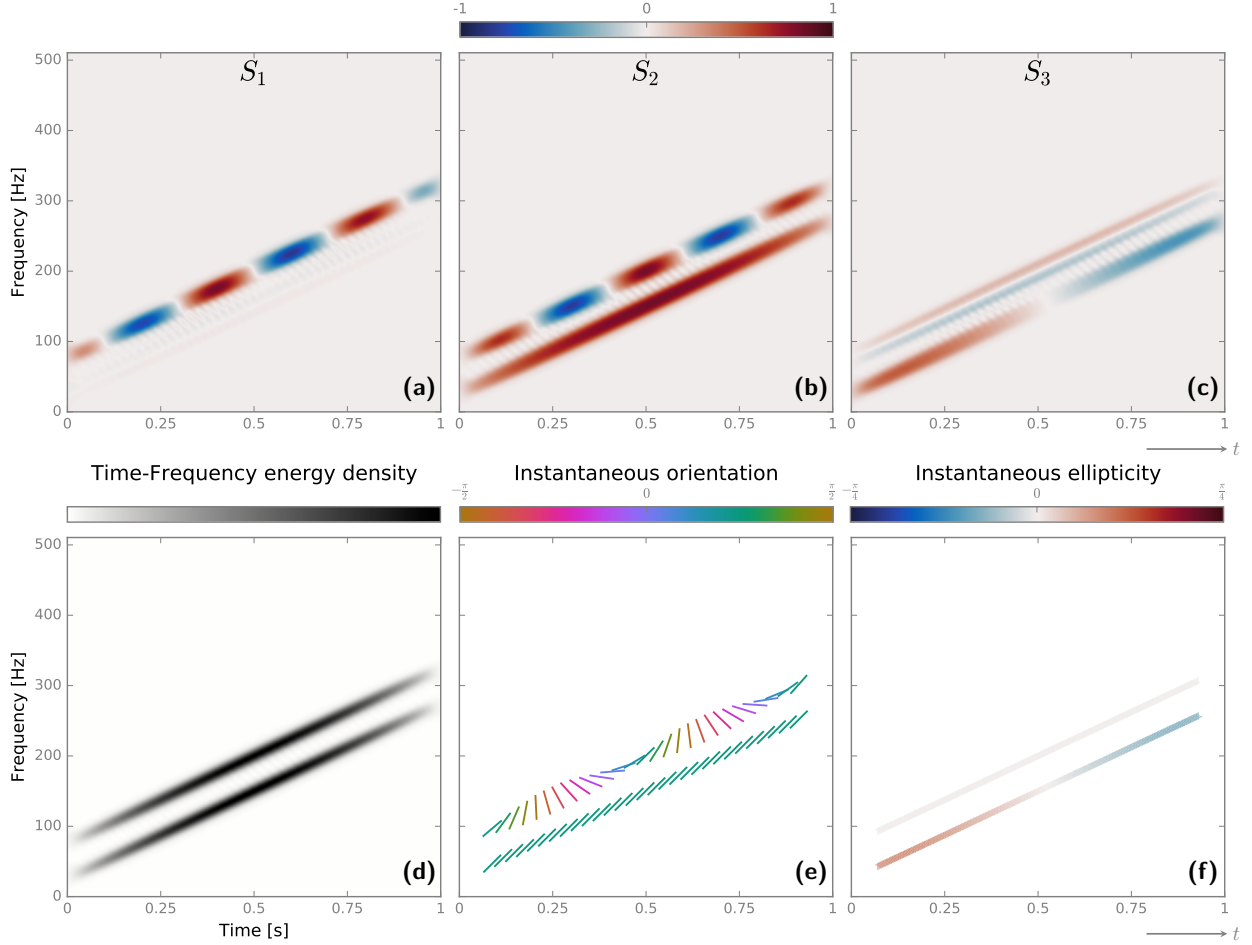

Figure 4: Sum of two polarized linear chirp and its two polarization spectrogram representation. (a), (b) and (c) Stokes parameters in the time-frequency plane. (d) Time-frequency energy density (e) instantaneous orientation on the ridge (f) instantaneous ellipticity on the ridge. Top chirp is linearly polarized, whereas the bottom chirp shows a slowly varying ellipticity.

The three Stokes parameters provide a reading of time-frequency-polarization properties of the two chirps. They have been normalized to be meaningfully interpreted. We have normalized S_1 , S_2 and S_3 by S_0 which is simply the time-frequency energy density depicted in figure 4d. While S_3 is directly an image of the ellipticity, the orientation has to be recovered by simultaneously inspecting the three Stokes parameters.

The time-frequency energy density permits the identification of the two linear chirps. This time-frequency energy density can be retrieved from the three Stokes parameters, as $S_0^2 = S_1^2 + S_2^2 + S_3^2$. Moreover, 4e, 4f show instantaneous orientation and ellipticity extracted from the ridge. The polarization properties of each chirp are correctly recovered.

6.2. Sum of hyperbolic polarized chirps

Consider two hyperbolic chirps, each having its own polarization properties. The signal is defined on the time interval $[0, 1]$, with $N = 1024$ samples. It can be written as the superposition $f(t) = f_1(t) + f_2(t)$,

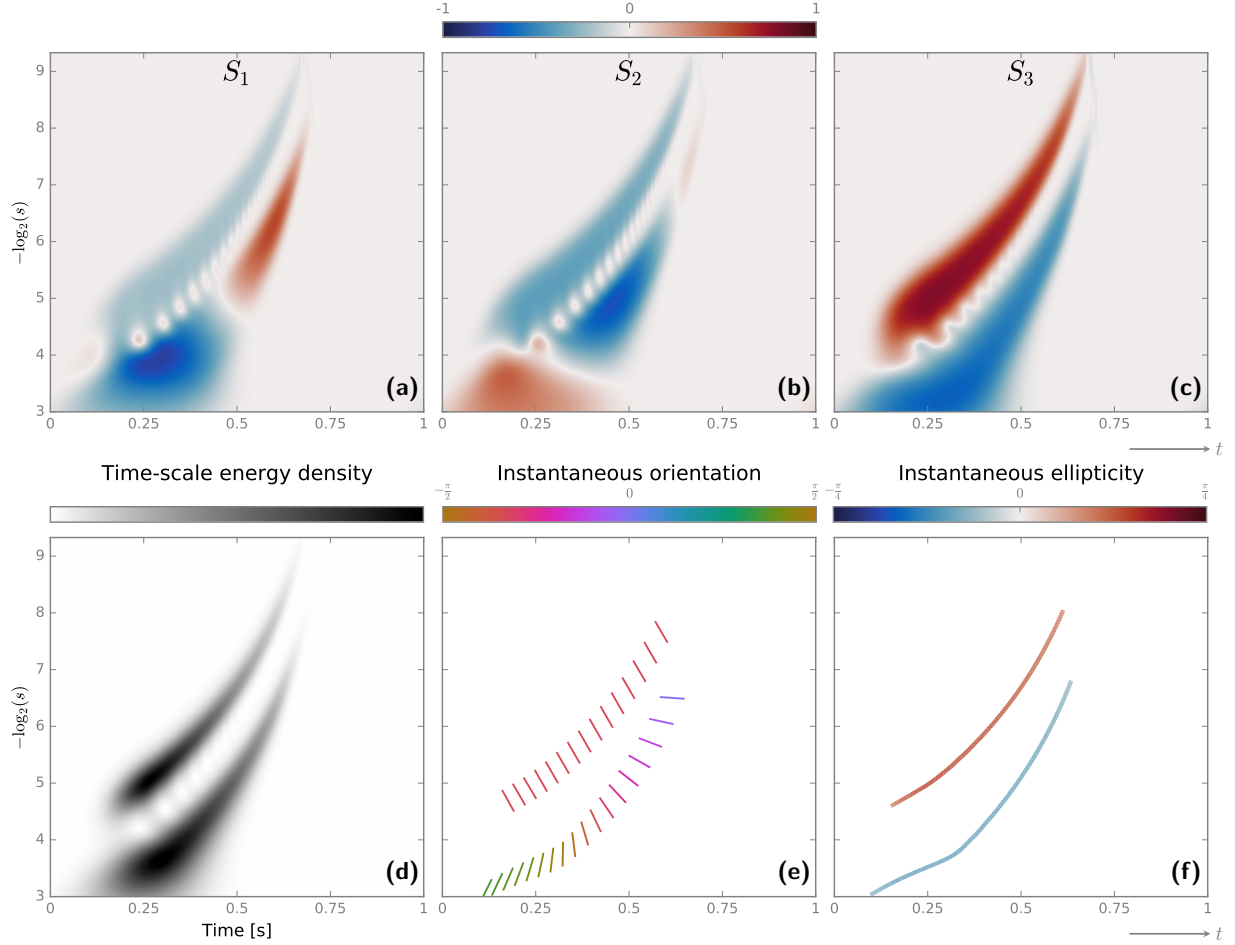

Figure 5: Sum of two polarized hyperbolic chirps and its polarization scalogram representation. (a), (b) and (c) Stokes parameters in the time-scale plane. (d) Time-scale energy density (e) instantaneous orientation on the ridge (f) instantaneous ellipticity on the ridge. Top chirp shows positive ellipticity, whereas the bottom chirp shows a negative one.

where the polar Euler decomposition are

$$\theta_1(t) = -\frac{\pi}{3}, \chi_1(t) = \frac{\pi}{6}, \varphi_1(t) = \frac{15\pi}{0.8-t} \quad (81)$$

$$\theta_2(t) = 5t, \chi_2(t) = -\frac{\pi}{10}, \varphi_2(t) = \frac{5\pi}{0.8-t}. \quad (82)$$

The Q-CWT was computed using a Morlet wavelet with $\eta = 5$.

Figure 5 shows the two equivalent polarization scalograms of f . Figure 5a, b, and c represent the three time-scale Stokes parameters S_1 , S_2 , S_3 . Figure 5d, e and f give the equivalent representation using the time-scale energy density, and the instantaneous orientation and ellipticity extracted from the ridge. The polarization properties of each chirp are correctly recovered.

These two examples validate the use of the Q-STFT and Q-CWT representations for nonstationary bivariate signals. Time-frequency (resp. time-scale) resolution is governed by the choice of the window (resp. wavelet), so that usual trade-offs apply.

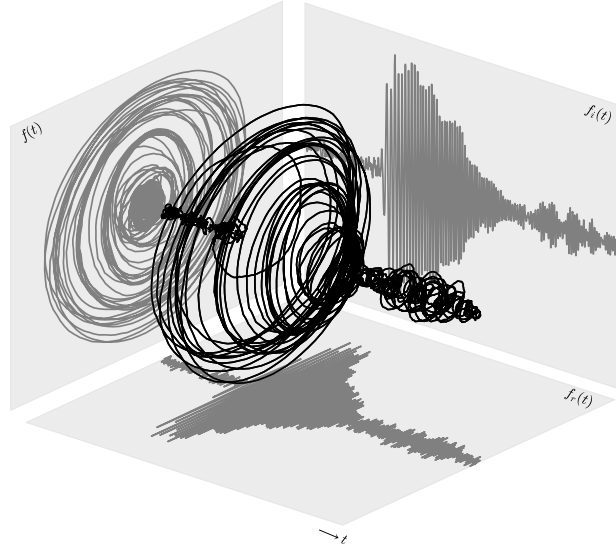

Figure 6: Seismic trace from the 1991 Solomon Islands Earthquake. For clarity, the bivariate signal has been developed in time along the third direction. Projection planes show respectively its complex plane trace, as well as real and imaginary components evolving with time.

6.3. A real world example

Figure 6 shows a seismic trace of the 1991 Solomon Islands Earthquake. This signal has already been studied by several authors [12, 42, 43]. Data is available as part of JLab [44]. It displays the time evolution of the process $f(t) = y(t) + ir(t)$, where y is the vertical component and r is the radial component. The part of the signal which is represented contains $N = 9000$ samples, equispaced by 0.25 s. . Figure 6 suggests that the signal is on average elliptically polarized, whereas the instantaneous orientation does not appear clearly from the seismic trace.

The Q-STFT of the signal has been computed using a Hanning window of size 801 samples, with window spacing equal to 10 samples. The Q-CWT of the signal has been computed on 200 scales, and using a Morlet wavelet with $\eta = 5$.

Figure 7 and 8 depict respectively polarization spectrograms and polarization scalograms of f . In Figure 7d and 8d, the ridge has been represented on top of the time-frequency/time-scale energy density. Figure 7e, f and 8e, f show the instantaneous orientation and ellipticity on the ridge.

From the ridge, this signal can be described in first approximation as a slow linear chirp in frequency. Moreover, as seen in both descriptions – Q-STFT and Q-CWT – the orientation of the signal remains constant in the most energetic part, around the vertical axis. The instantaneous ellipticity is on average equal to $\chi \simeq \pi/5$, confirming the elliptical polarization obtained by visual inspection of figure 6. However, we also see that the instantaneous ellipticity reaches sporadically $\simeq \pi/4$ (almost circular polarization) and $\simeq 0^+$ (almost linear polarization), thus revealing more details about the signal.

7. Conclusion

We have proposed a generalization of time-frequency analysis to bivariate signals. Our approach is based on the use of a Quaternion Fourier Transform (QFT). It appears that, despite the apparent complexity of the quaternion algebra due to non-commutativity, the natural extension of usual definitions leads to a bivariate time-frequency toolbox with nice properties. This new framework interestingly includes the usual univariate Fourier analysis. Heisenberg’s uncertainty principle is again supported by Gabor’s theorem. The definition of the quaternion embedding, a counterpart of the analytic signal for bivariate signals, yields a natural elliptic description of the instantaneous polarization state thanks to the Euler polar form. As a consequence we have

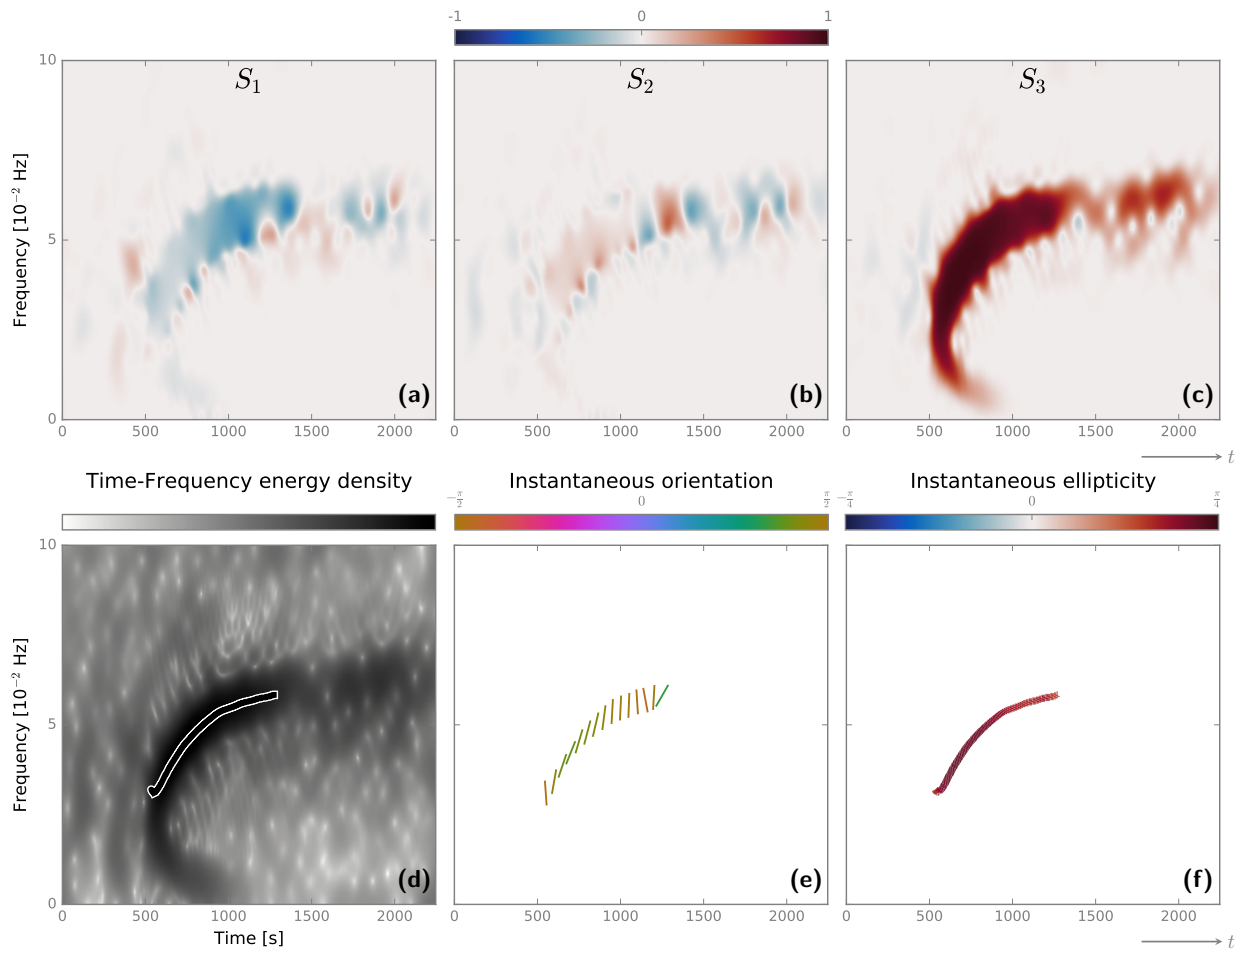

Figure 7: Polarization spectrogram of the Solomon Earthquake dataset (a), (b) and (c) Stokes parameters in the time-frequency plane. (d) Time-frequency energy density (e) instantaneous orientation on the ridge (f) instantaneous ellipticity on the ridge.

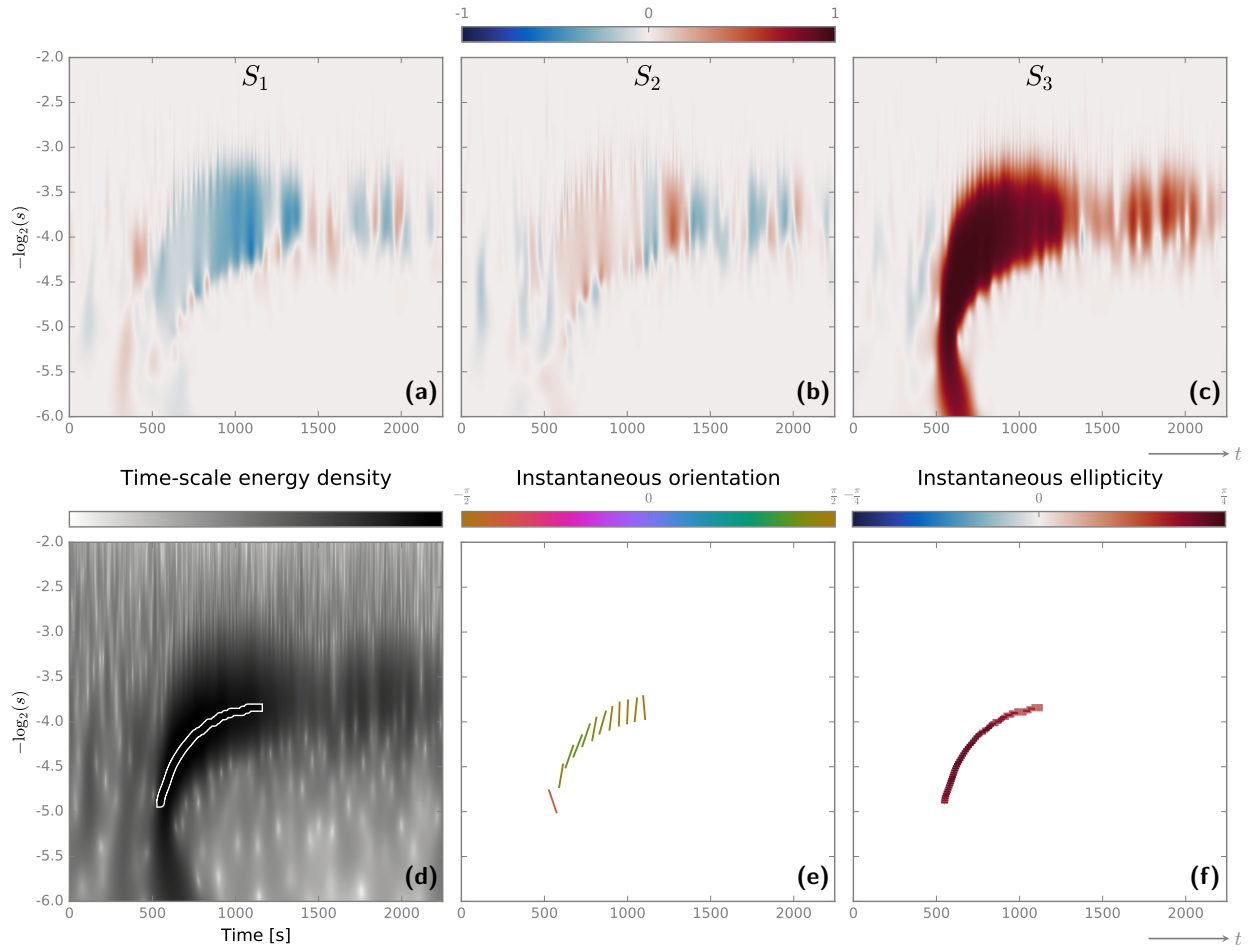

Figure 8: Polarization scalogram of the Solomon Earthquake dataset ((a), (b) and (c) Stokes parameters in the time-scale plane. (d) Time-scale energy density (e) instantaneous orientation on the ridge (f) instantaneous ellipticity on the ridge.

introduced instantaneous Stokes parameters, the relevant physical quantities to describe the polarization state of polarized waves.

Turning to time-frequency representations, we have defined a quaternion short term Fourier transform (Q-STFT) and a quaternion continuous wavelet transform (Q-CWT) as simple generalizations of the usual definitions by using the QFT in place of the usual Fourier transform. This extension permits to show fundamental theorems on the conservation of energy and polarization quantities as well as reconstruction formulas. These theorems permit the definition of spectrograms and scalograms, including the representation of the evolution of the polarization state in the time-frequency plane. These spectrogram and scalogram possess an underlying RKHS structure.

In practice, due to Gabor's theorem, spectrograms and scalograms are never perfectly localized so that one often needs to extract ridges to accurately identify the time-frequency content of the signal. Classical ridge extraction algorithms apply to the present framework. The application of the proposed toolbox to synthetic as well as real world data has demonstrated the efficiency of the proposed approach. The resulting graphical representations make the time-frequency content of bivariate signals very readable and intelligible. On a practical ground, the numerical implementation remains simple and cheap since it relies on the use of a few fast Fourier transforms. The proposed tools are available as part of the open-source **BisPy** python package⁴.

We emphasize the general relevance and efficiency of the proposed approach to analyze a wide class of bivariate signals without any *ad hoc* model. This approach is very generic. We believe that it will be useful in many applications where the joint time-frequency analysis of 2 components is required. Moreover this work paves the way to the definition of even more general tools to deal with either bivariate signals in dimension larger than 1 or multivariate signals with values in a D-dimensional space with $D \geq 2$.

Appendix A. Quaternion Fourier Transform related proofs

Appendix A.1. Proof of Theorem 1

Since Plancherel formulas can be obtained directly with $f = g$ in Parseval formulas, we only give a proof for Parseval's formulas. Let $f, g \in L^2(\mathbb{R}, \mathbb{H})$. We have

$$\int_{-\infty}^{+\infty} f(t)g(t)^{*}\mu dt = \frac{1}{2\pi} \int \left(\int \hat{f}(\omega)e^{\mu\omega t} d\omega \right) g(t)^{*}\mu dt \quad (\text{A.1})$$

$$(\forall a, b \in \mathbb{H}, (ab)^{*}\mu = b^{*\mu}a^{*\mu}) = \frac{1}{2\pi} \iint \hat{f}(\omega)(g(t)e^{-\mu\omega t})^{*\mu} dt d\omega \quad (\text{A.2})$$

$$= \frac{1}{2\pi} \int \hat{f}(\omega) \left(\int g(t)e^{-\mu\omega t} dt \right)^{*}\mu d\omega \quad (\text{A.3})$$

$$= \frac{1}{2\pi} \int \hat{f}(\omega)\hat{g}(\omega)^{*}\mu d\omega. \quad (\text{A.4})$$

The other equality is proven analogously.

⁴Code is available at <https://github.com/jflamant/bispy> and documentation at <http://bispy.readthedocs.io/>.

Appendix A.2. Proof of Proposition 1

Let $f \in L^2(\mathbb{R}, \mathbb{H})$, $g \in L^2(\mathbb{R}, \mathbb{C}_\mu)$ and \mathcal{F} denote the QFT of axis μ . A direct calculation gives

$$\mathcal{F}\{f * g\}(\omega) = \int \left(\int f(u)g(t-u)du \right) \exp(-\mu\omega t)dt \quad (\text{A.5})$$

$$= \int f(u)\hat{g}(\omega) \exp(-\mu\omega u)du \quad (\text{A.6})$$

$$= \hat{f}(\omega)\hat{g}(\omega) \quad (\text{A.7})$$

where we have used the fact that $\hat{g}(\omega)$ and $\exp(-\mu\omega u)$ commute, since \mathbb{C}_μ is an invariant subspace of the QFT of axis μ .

Appendix A.3. Proof of Theorem 2

Let $f \in L^2(\mathbb{R}, \mathbb{H})$ and denote its QFT by \hat{f} . Using a change of variable, it is sufficient to prove the theorem in the case where $u = \xi = 0$. First let us note that

$$\sigma_t^2 \sigma_\omega^2 = \frac{1}{2\pi \|f\|^4} \int_{-\infty}^{+\infty} |tf(t)|^2 dt \int_{-\infty}^{+\infty} |\omega \hat{f}(\omega)|^2 d\omega \quad (\text{A.8})$$

Since $\hat{f}(\omega)\mu\omega$ is the Fourier transform of $f'(t)$, using the Plancherel identity applied to $\hat{f}(\omega)\mu\omega$ yields

$$\sigma_t^2 \sigma_\omega^2 = \frac{1}{\|f\|^4} \int_{-\infty}^{+\infty} |tf(t)|^2 dt \int_{-\infty}^{+\infty} |f'(t)|^2 dt \quad (\text{A.9})$$

Schwarz's inequality implies (legit since $L^2(\mathbb{R}, \mathbb{H})$ is a Hilbert space)

$$\sigma_t^2 \sigma_\omega^2 \geq \frac{1}{\|f\|^4} \left| \int_{-\infty}^{+\infty} f'(t) \overline{tf(t)} dt \right|^2 \quad (\text{A.10})$$

$$\geq \frac{1}{\|f\|^4} \left[\int_{-\infty}^{+\infty} \mathcal{S} \left(f'(t) \overline{tf(t)} \right) dt \right]^2 \quad (\text{A.11})$$

$$\geq \frac{1}{\|f\|^4} \left[\int_{-\infty}^{+\infty} \frac{t}{2} \left(f'(t) \overline{f(t)} + f(t) \overline{f'(t)} \right) dt \right]^2 \quad (\text{A.12})$$

$$\geq \frac{1}{4\|f\|^4} \left[\int_{-\infty}^{+\infty} t(|f(t)|^2)' dt \right]^2 \quad (\text{A.13})$$

$$(\text{A.14})$$

Now, using integration by parts we obtain

$$\sigma_t^2 \sigma_\omega^2 \geq \frac{1}{4\|f\|^4} \left[\int_{-\infty}^{+\infty} |f(t)|^2 dt \right]^2 = \frac{1}{4}. \quad (\text{A.15})$$

Appendix B. Time-frequency and time-scale representations: related proofs

Appendix B.1. Proof of Theorem 3

The time-frequency-polarization atoms $g_{u,\xi}$ are of the form $g_{u,\xi}(t) = g(t-u) \exp(j\xi t)$, where g is a real symmetric window. Let us rewrite the Q-STFT coefficients $Sf(u, \xi)$ like

$$\begin{aligned} Sf(u, \xi) &= \int_{-\infty}^{+\infty} f(t)g(t-u) \exp(-j\xi t)dt \\ &= \left(\int_{-\infty}^{+\infty} f(t)g(u-t) \exp[j\xi(u-t)]dt \right) \exp(-j\xi u) \\ &= (f * g_{0,\xi})(u) \exp(-j\xi u) \end{aligned} \quad (\text{B.1})$$

where $g_{0,\xi}(t) = g(t) \exp(j\xi t)$. The QFT of this expression yields

$$\begin{aligned} \int_{-\infty}^{+\infty} Sf(u, \xi) \exp(-j\omega u) du &= \int_{-\infty}^{+\infty} (f * g_{0,\xi})(u) \exp(-j(\omega + \xi)u) du \\ &= \hat{f}(\omega + \xi) \hat{g}_{0,\xi}(\omega + \xi) \\ &= \hat{f}(\omega + \xi) \hat{g}(\omega) \end{aligned} \quad (\text{B.2})$$

thanks to the convolution property (Prop. 1) of the QFT. Parseval's formula with respect to u yields

$$\int_{-\infty}^{+\infty} Sf(u, \xi) g(t - u) du = \frac{1}{2\pi} \int_{-\infty}^{+\infty} [\hat{f}(\omega + \xi) \hat{g}(\omega)] e^{j t \omega} \overline{\hat{g}(\omega)} d\omega \quad (\text{B.3})$$

Since g is real, its QFT is \mathbb{C}_j -valued, it commutes with the exponential kernel, *i.e.* $e^{j t \omega} \overline{\hat{g}(\omega)} = \overline{\hat{g}(\omega)} e^{j t \omega}$. We conclude the proof of the inversion formula (51) according to the following lines by using that $\|g\| = 1$:

$$\begin{aligned} \frac{1}{2\pi} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} Sf(u, \xi) g(t - u) e^{j \xi t} du d\xi &= \frac{1}{4\pi^2} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} [\hat{f}(\omega + \xi) \hat{g}(\omega)] \overline{\hat{g}(\omega)} e^{j t (\omega + \xi)} d\omega d\xi \\ &= \frac{1}{4\pi^2} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} \hat{f}(\omega + \xi) |\hat{g}(\omega)|^2 e^{j t (\omega + \xi)} d\omega d\xi \\ &= \frac{1}{2\pi} \int_{-\infty}^{+\infty} f(t) |\hat{g}(\omega)|^2 d\omega \\ &= f(t) \end{aligned} \quad (\text{B.4})$$

From (B.2) we know that the QFT of $Sf(u, \xi)$ with respect to u is $\hat{f}(\omega + \xi) \hat{g}(\omega)$. Then using the usual Plancherel's formula in u yields

$$\begin{aligned} \frac{1}{2\pi} \iint |Sf(u, \xi)|^2 du d\xi &= \frac{1}{2\pi} \int \frac{1}{2\pi} \int |\hat{f}(\omega + \xi) \hat{g}(\omega)|^2 d\omega d\xi \\ &= \frac{1}{2\pi} \int \frac{1}{2\pi} \int |\hat{f}(\omega) \hat{g}(\omega - \xi)|^2 d\omega d\xi \\ &= \frac{1}{2\pi} \int |\hat{f}(\omega)|^2 d\omega \\ &= \|f\|^2. \end{aligned} \quad (\text{B.5})$$

which concludes the proof of the energy conservation property (52). The polarization conservation property (53) is proven along the same lines using the second Plancherel formula in (16). \square

Appendix B.2. Proof of Theorem 4

We first prove a preliminary result. The polarization wavelets ψ are \mathbb{C}_j -valued and we use the notation $\psi_s(t) = s^{-1/2} \psi(t/s)$. Let $f_s(u) = Wf(u, s)$ the wavelet coefficients at scale s . The QFT with respect to u is

$$\begin{aligned} \hat{f}_s(\omega) &= \int_{-\infty}^{+\infty} Wf(u, s) \exp(-j\omega u) du \\ &= \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} f(t) \overline{\psi_s(t - u)} \exp(-j\omega u) du dt \\ &= \int_{-\infty}^{+\infty} f(t) \left(\int_{-\infty}^{+\infty} \overline{\psi_s(t - u)} \exp(-j\omega u) du \right) dt \\ &= \left(\int_{-\infty}^{+\infty} f(t) \exp(-j\omega t) dt \right) \overline{\hat{\psi}_s(\omega)} \\ &= \underbrace{\hat{f}(\omega)}_{\in \mathbb{H}} \underbrace{\overline{\hat{\psi}_s(\omega)}}_{\in \mathbb{C}_j} \end{aligned} \quad (\text{B.6})$$

Let us consider the quantity $b(t)$

$$b(t) = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} Wf(u, s) \psi_s(t - u) du \frac{ds}{s^2} \quad (\text{B.7})$$

Taking the QFT of $b(t)$ yields

$$\begin{aligned} \hat{b}(\omega) &= \int_{-\infty}^{+\infty} \left(\int_{-\infty}^{+\infty} \int_0^{+\infty} Wf(u, s) \psi_s(t - u) du \frac{ds}{s^2} \right) \exp(-j\omega t) dt \\ &= \int_{-\infty}^{+\infty} \int_0^{+\infty} Wf(u, s) \left(\int_{-\infty}^{+\infty} \psi_s(t - u) \exp(-j\omega t) dt \right) du \frac{ds}{s^2} \\ &= \int_{-\infty}^{+\infty} \int_0^{+\infty} Wf(u, s) \hat{\psi}_s(\omega) \exp(-j\omega u) du \frac{ds}{s^2} \\ &= \int_{-\infty}^{+\infty} \int_0^{+\infty} Wf(u, s) \exp(-j\omega u) \hat{\psi}_s(\omega) du \frac{ds}{s^2} \\ &= \int_0^{+\infty} \hat{f}(\omega) \overline{\hat{\psi}_s(\omega)} \hat{\psi}_s(\omega) \frac{ds}{s^2} \end{aligned} \quad (\text{B.8})$$

so that

$$\hat{b}(\omega) = \hat{f}(\omega) \int_{-\infty}^{+\infty} \frac{|\hat{\psi}(\xi)|^2}{\xi} d\xi = \hat{f}(\omega) C_\psi, \quad (\text{B.9})$$

If the admissibility condition is satisfied (if C_ψ is finite), $f_+(t)$ and $C_\psi^{-1}b(t)$ have the same Fourier transforms. This proves the inversion formula (64).

$$f(t) = \frac{1}{C_\psi} \int_{-\infty}^{+\infty} \int_0^{+\infty} Wf(u, s) \psi_s(t - u) du \frac{ds}{s^2}. \quad (\text{B.10})$$

Turning to the energy conservation property (65), we write according to the first Plancherel's formula (16)

$$\frac{1}{C_\psi} \int_{-\infty}^{+\infty} \int_0^{+\infty} |Wf_+(u, s)|^2 du \frac{ds}{s^2} = \frac{1}{C_\psi} \int_{-\infty}^{+\infty} \int_0^{+\infty} |\hat{f}_+(\omega) \overline{\hat{\psi}_s(\omega)}|^2 d\omega \frac{ds}{s^2} \quad (\text{B.11})$$

Simplifying this expression yields

$$\frac{1}{C_\psi} \int_{-\infty}^{+\infty} \int_0^{+\infty} |Wf_+(u, s)|^2 du \frac{ds}{s^2} = \int_{-\infty}^{+\infty} |\hat{f}_+(\omega)|^2 d\omega = \|f_+\|^2 \quad (\text{B.12})$$

which proves (65). The conservation of polarization properties (66) is obtained following the same lines. \square

Appendix C. Stationary phase approximation

Appendix C.1. Principle

We will need a stationary phase approximation to study the localization of ridges in spectrograms and scalograms. We briefly recall the stationary phase approximation [45]. This argument is based on [38], adapted to the case of the QFT. Let us consider the integral

$$I = \int_{-\infty}^{+\infty} A(t) e^{j\varphi(t)} dt, \quad (\text{C.1})$$

where $A \in \mathcal{C}_0^\infty(\mathbb{R}, \mathbb{H})$, which ensures that $|A(t)| \rightarrow 0$ as $t \rightarrow \pm\infty$, and $\varphi \in C^\infty(\mathbb{R}, \mathbb{R})$. We assume moreover that the function φ is varying much faster than variations of A . Let τ be a stationary point of φ such that is

$\varphi'(\tau) = 0$. Assume that τ is unique, otherwise the contributions of all stationary points must be summed up. Then, if the conditions of a stationary phase approximation are valid, the change of variable

$$u(t) = \frac{1}{\sqrt{2}} (-j \operatorname{sign}(\varphi''(\tau)) |\varphi''(\tau)|)^{1/2} (t - \tau) \quad (\text{C.2})$$

permits to get the following approximation

$$I \simeq A(\tau) e^{j\varphi(\tau)} \int_{u(\mathbb{R})} e^{-u^2} \left(\frac{du}{dt} \right)^{-1} du. \quad (\text{C.3})$$

Then, thanks to usual results on Gaussian integrals one gets

$$I \simeq \sqrt{2\pi} \frac{A(\tau)}{\sqrt{|\varphi''(\tau)|}} e^{j \operatorname{sign}(\varphi''(\tau)) \frac{\pi}{4}} e^{j\varphi(\tau)}. \quad (\text{C.4})$$

Appendix C.2. Q-STFT asymptotic analysis

For sake of simplicity, we restrict our analysis to points $(u, \xi) \in \Omega \subset \mathcal{P}$ such that the time-frequency-polarization atoms $g_{u,\xi}$ belong to the Hardy space $H^2(\mathbb{R}, \mathbb{C}_j)$, see (38). This restriction ensures that $g_{u,\xi}$ features positive frequencies only so that $\forall (u, \xi) \in \Omega$,

$$Sf(u, \xi) = \frac{1}{2} Sf_+(u, \xi). \quad (\text{C.5})$$

We consider bivariate AM-FM signals $f(t)$ such that (41) is valid. The aim of this section is to show that Q-STFT ridges of these signals concentrate on the local instantaneous frequency $\varphi'(u)$ at time u . We start from

$$Sf(u, \xi) = \frac{1}{2} \langle f_+, g_{u,\xi} \rangle = \frac{1}{2} \int_{-\infty}^{+\infty} f_+(t) g(t-u) e^{-j\xi t} dt. \quad (\text{C.6})$$

Recall that $f_+(t) = a(t) \exp(j\theta(t)) \exp(-k\chi(t)) \exp(j\varphi(t))$ so that

$$Sf(u, \xi) = \frac{1}{2} \int_{-\infty}^{+\infty} a(t) e^{j\theta(t)} e^{-k\chi(t)} g(t-u) e^{j(\varphi(t)-\xi t)} dt. \quad (\text{C.7})$$

This expression is an oscillatory integral that can be approximated using a stationary phase argument, see Appendix C.1 above. Let $\Phi_\xi(t) = \varphi(t) - \xi t$, and denote $\tau = \tau(\xi)$ a stationary phase point such that $\Phi'_\xi(\tau) = 0$. We assume that $\tau(\xi)$ is unique for each ξ and that $\Phi''_\xi(\tau) \neq 0$ for simplicity⁵. The stationary phase approximation reads

$$Sf(u, \xi) \simeq \sqrt{\frac{\pi}{2}} \frac{a(\tau) e^{j\theta(\tau)} e^{-k\chi(\tau)} g(\tau-u)}{\sqrt{|\varphi''(\tau)|}} e^{\operatorname{sign}(\varphi''(\tau)) j \frac{\pi}{4}} e^{j(\varphi(\tau)-\xi\tau)} \quad (\text{C.8})$$

which can be rewritten as

$$Sf(u, \xi) \simeq f_+(\tau) \cdot \sqrt{\frac{\pi}{2}} \frac{g(\tau-u)}{\sqrt{|\varphi''(\tau)|}} e^{\operatorname{sign}(\varphi''(\tau)) j \frac{\pi}{4}} e^{-j\xi\tau}. \quad (\text{C.9})$$

The last equation shows that the approximation involves the computation of the quaternion embedding at stationary points only. This is a straightforward generalization of classical results on the analytic signal [38]. The *ridge* of the transform is the set of points $(u, \xi) \in \Omega$ such that $\tau(\xi) = u$. On the ridge, one has

$$\xi_{\text{ridge}}(u) = \varphi'(u), \quad (\text{C.10})$$

which corresponds to the instantaneous frequency of an AM-FM signal. The restriction of the Q-STFT to the ridge then is

$$Sf(u, \xi_{\text{ridge}}(u)) \simeq f_+(u) \cdot \sqrt{\frac{\pi}{2}} \frac{g(0)}{\sqrt{|\varphi''(u)|}} e^{\operatorname{sign}(\varphi''(u)) j \frac{\pi}{4}} e^{-j\xi u}. \quad (\text{C.11})$$

⁵If there are multiple stationary points, one must sum their contributions. Also, if $\Phi''_\xi(\tau) = 0$, then we search the smallest $k \geq 2$ such that $\Phi_\xi^{(k)}(\tau) \neq 0$. Formula follow by straightforward adjustment.

Appendix C.3. Q-CWT asymptotic analysis

Let $\psi \in H^2(\mathbb{R}, \mathbb{C}_j)$ be an admissible wavelet, and let $f \in L^2(\mathbb{R}, \mathbb{H})$. One has

$$Wf(u, s) = \frac{1}{2} Wf_+(u, s). \quad (\text{C.12})$$

In polar form, $\psi(t) = |\psi(t)| \exp(j\varphi_\psi(t))$ and the wavelet transform reads

$$Wf(u, s) = \frac{1}{2\sqrt{s}} \int_{-\infty}^{+\infty} f_+(t) \overline{\psi\left(\frac{t-u}{s}\right)} dt. \quad (\text{C.13})$$

Using the Euler polar form of $f_+(t)$ yields

$$Wf(u, s) = \frac{1}{2\sqrt{s}} \int_{-\infty}^{+\infty} a(t) e^{i\theta(t)} e^{-k\chi(t)} \left| \psi\left(\frac{t-u}{s}\right) \right| e^{j(\varphi(t) - \varphi_\psi[(t-u)/s])} dt. \quad (\text{C.14})$$

This is an oscillatory integral, which is approximated using formula (C.4). For $(u, s) \in \mathcal{P}$ we assume that $\tau = \tau(u, s)$ is the unique stationary point of $\Phi_{u,s}(t) = \varphi(t) - \varphi_\psi[(t-u)/s]$ such that $\Phi'_{u,s}(\tau) = 0$ and $\Phi''_{u,s}(\tau) \neq 0$. Then

$$Wf(u, s) \simeq \sqrt{\frac{\pi}{2s}} f_+(\tau) \frac{1}{\sqrt{|\Phi''_{u,s}(\tau)|}} \overline{\psi\left(\frac{\tau-u}{s}\right)} e^{\text{sign}(\Phi''_{u,s}(\tau)) j \frac{\pi}{4}} \quad (\text{C.15})$$

The ridge of the transform is the set of points $(u, s) \in \mathcal{P}$ such that $\tau(u, s) = u$. On the ridge, one has

$$s_{\text{ridge}}(u) = \frac{\varphi'_\psi(0)}{\varphi'(u)}, \quad (\text{C.16})$$

which corresponds to the instantaneous frequency of the signal f . The restriction of the wavelet transform to the ridge is:

$$Wf(u, s_{\text{ridge}}(u)) \simeq \sqrt{\frac{\pi}{2s_{\text{ridge}}(u)}} f_+(u) \frac{1}{\sqrt{|\Phi''_{u,s_{\text{ridge}}(u)}(u)|}} \overline{\psi(0)} e^{\text{sign}(\Phi''_{u,s_{\text{ridge}}(u)}(u)) j \frac{\pi}{4}}. \quad (\text{C.17})$$

Here we mostly consider wavelet modulated windows $\psi(t) = g(t) \exp(j\eta t)$, where g is a real symmetric window and $\eta > 0$ is the central frequency such that ψ belongs to $H^2(\mathbb{R}, \mathbb{C}_j)$. In this case, equation (C.17) can be rewritten as

$$Wf(u, s_{\text{ridge}}(u)) \simeq f_+(u) \cdot \sqrt{\frac{\pi}{2s_{\text{ridge}}(u)}} \frac{g(0)}{\sqrt{|\varphi''(u)|}} e^{\text{sign}(\varphi''(u)) j \frac{\pi}{4}}. \quad (\text{C.18})$$

Appendix D. Efficient implementation of the QFT using complex FFTs

The discrete QFT can be computed easily using the standard complex FFT algorithm. In the general case where f is \mathbb{H} -valued, one can write the function f in the following manner

$$f(t) = f_s(t) + \mathbf{i} f_p(t) \quad (\text{D.1})$$

where f_s and f_p are called *simplex* and *perplex* parts, respectively, and are both \mathbb{C}_j -valued functions. We note that this decomposition highly resemble the Cayley-Dickson decomposition. Similarly we can write the symplectic decomposition of the QFT of f , such that

$$\hat{f}(\omega) = \hat{f}_s(\omega) + \mathbf{i} \hat{f}_p(\omega), \quad (\text{D.2})$$

with $\hat{f}_s(\omega)$, $\hat{f}_p(\omega)$ both \mathbb{C}_j -valued. Therefore it is sufficient to compute two FFTs: one on the simplex part and the other one on the perplex part. The procedure for the inverse QFT is similar. Thus the complexity of the discrete QFT algorithm is the same as that of the standard FFT algorithm, that is $\mathcal{O}(N \log N)$.
